Salt added to baths increases the effect of cold. Zunts found that in a three-per-cent. saline bath there was an increase of oxidation, as compared with a fresh-water bath, so that fifteen per cent. more oxygen was used and twenty-five per cent. more CO_2 was given off. This effect could not be obtained if the nerve ends were paralyzed with curare. Agents which, like the saline bath, bring about increased metabolism are:

1. Sea air, which, however, diminishes the amount of phosphoric acid excreted and stimulates the nervous system constantly without a decided or permanent effect upon the circulation. 2. The drinking of cold water, which increases tissue change by depriving the body of heat, but is not well borne by the digestive tract. 3. Physical exercise, which, however, demands the increased use of energy, increases the amount of phosphoric acid excreted, and is decidedly contraindicated in inflammatory pelvic conditions.

Simple rest causes no increased tissue change, has constitutionally no effect on the general tone, rests the nervous system, but is accompanied by no stimulating action on the same. A bath containing, in addition to salt, calcium chloride, which exerts reflexly a decided action on the breaking down of old tissue, and CO_2 brings about most valuable results. Its action follows the law of normal body stimuli and causes a relief and rest for the heart, since the chemical elements and the CO_2 dilate the peripheral vessels, carry the blood into the vessels of the muscles, relieve the interior of the body of congestions, and cool it on the return of the blood. The effect upon metabolism and tissue change is here not brought about through exertion or through the giving off of reserve energy, but through the channels of protection and tissue substitution. This regulated and altered tissue change goes on within a certain physiological limit, which does not endanger or overtax the functional energies of the body. However low the temperature of the bath may gradually be reduced, a frottement is always brought about through the action of the chlorides and the free CO_2.

Beneke, in 1859, minutely studied the action of such baths and gave them a decided scientific basis. The advances in later years have proven that the neurotherapeutic value of such baths is an important factor, since reflexly the entire nervous system and the trophic centres are greatly stimulated, especially by the CO_2.

A fifty-gallon bath containing among other ingredients five pounds of sodium chloride and ten ounces of calcium chloride with some CO_2, that is, a Nauheim bath of a temperature of 27° R., was found to cause a slight daily increase of tissue metabolism. The degree or intensity of this change varies, however, considerably at certain periods of the day. The increase of tissue change causes an increased demand for nutrition and is accompanied by an increase in the amount of kidney secretion. The excretion of urea is slightly increased, the excretion of phosphoric acid is diminished. The immediate effect of such a bath is a diminution in the frequency of the pulse and in the number of respirations. Tissue metabolism is immediately stimulated, for during the hours directly following a bath most of the solid constituents are excreted in the urine. In the later hours metabolism possesses a slighter intensity than during the same hours and days when no baths are taken. The diminution in the amount of phosphoric acid excreted is one of the important effects, and stands in relation to the benefits which later result to the body nutrition. The increased amount of this substance in the body stimulates the further production of new tissue and is of the greatest importance in determining the quality of the structures which replace the broken-down tissues. If the broken-down tissues are substances of an abnormal character, and if the substituted nutrition is of a character suited to the building up of normal structures, then this element in combination with the phosphoric acid offers valuable restoration to the body. The amount of carbonic-acid gas excreted through the skin, and especially through the lungs, is shown through the frequent occurrence of fetid expiration after a bath, a process which can be attributed to an oxidation, among other things, of organic acids. A retarded metamorphosis of the organic acids is often found in persons with a weak nervous system, in large eaters, and in many cases of anæmia. If the amount of the saline ingredients of the bath is increased, there results a slight increase of the various effects. There may be a still further demand for nutrition, the secretion of the kidney is increased, but the amount of phosphoric acid excreted may be greater than normally; therefore the subjective feeling varies, and there occurs easily a feeling of weariness and lassitude. The effect depends greatly upon individual qualities. If there is, with stronger baths, no over-stimulation, then the good results persist. If there is, on the contrary, an over-stimulation, then comes a weakening effect with evidences of nervousness, sleeplessness, loss of appetite, etc.

There is, therefore, for every individual a certain limit beyond which an increase of tissue change and nerve stimulation must not be carried, and the above-mentioned symptoms, together with the increased excretion of phosphoric acid, are evidences of too strong baths.

The power of these baths in aiding resorption is evidenced by the results obtained by Beneke in the treatment of rheumatism and gout. Almost without exception the rheumatic symptoms in the joints disappeared after a course of baths. Recurrences rarely developed. The heart action was always quieted, and anæmic and run-down patients improved rapidly. If the inflammation centre was changed to real connective tissue, or was retracted and sclerosed, it was then difficult to obtain improvement. If this centre, on the contrary, was fresh, then it was, as a rule, capable of resorption. The baths were well borne after the acute symptoms were overcome. These two- to four-per-cent. saline baths, slightly carbonated, of a temperature between 27°–25° R., were well borne by the severest

heart cases. The resorption of serous transudates and joint exudates was truly astonishing. A partial or complete resorption of the endocardial growth was found to be more certain, the nearer to the acute attack the baths were begun, and the improvement in the condition of delicate persons was so rapid that Beneke deemed it dependent upon other influences than increased tissue metamorphosis. It is this element, namely, the stimulation of the trophic centres through the salts, and most especially through the CO_2 upon which Graupner lays stress, using as an example the vast and decided improvement in cases of locomotor ataxia.

The action of CO_2 is to produce a feeling of warmth, and a dilatation of the capillaries of the skin and of the peripheral vessels. After a bath the CO_2 causes a feeling of exhilaration, provided the amount of CO_2 and the duration of the bath be not too great.

The action of these thermal carbonated saline baths brings about the following results: (1) Slowing of the pulse and respiration; (2) increased oxidation; (3) increased diuresis; (4) a saving of phosphoric acid; (5) rest and protection for the heart; (6) regulation of the circulation and a subsequent strengthening of the heart through increased tonus of the entire circulatory system, and through the removal of congestions; (7) an increase in the number of red blood cells; (8) a building up of healthy tissue; (9) an increased demand for nutrition; (10) a stimulation of the entire nervous system, especially the trophic centres; (11) the removal of congestion; (12) the resorption of exudates.

The value of these baths has been proven in amenorrhœa, in insufficient development of the genitalia, and in insufficient muscular condition of the uterus, with or without chlorotic symptoms. Uterine catarrh, depending upon a lack of elasticity of the pelvic organs, disturbances in the blood supply, and atony of the vessels, is greatly benefited by this treatment. The immediate effect can be recognized by the fact that often after a bath large amounts of mucus are discharged, caused by increased secretion and a stimulation of the con traction of the uterus. This latter action explains their value in cases of subinvolution. In chronic metritis the bath causes a diminution of hyperæmia, removes the collateral circulatory disturbances, and improves the general condition. This effect may be obtained so long as no interstitial hypertrophy exists. The older the affection, the more energetic must be the treatment. Cases of chronic metritis after repeated abortions, or during the climacterium, should not be treated with strong saline baths, since through a continued blood supply they are liable to exacerbations. Nervous individuals must be given graded treatment, and in these, as in anæmic cases, progress must be made slowly, for, as Graupner says, these are cases in which the entire energy of the body is consumed in preserving a balance between nutrition and the force used in the performance of the most necessary body functions, so that the slightest degree of overstimulation is of decided injury.

The first severe test to which I put the baths was in a case of pelvic cellulitis of gonorrhœal origin, with the most complete infiltration of the pelvic and parametric and perimetric tissue I have ever seen. Local treatment and rest in bed for two weeks having no effect, I sent her as a test case to Nauheim. On leaving, the uterus was so embedded that it could scarcely be made out from the surrounding perimetrium. It was as if the whole bottom of the pelvis were filled with plaster of Paris. The patient was pale, anæmic, without appetite, and completely despondent. After four weeks, during which she received twenty-two baths, beginning with the simple and finishing with the "Sprudel" bath, a marvellous improvement was found. The uterus was movable, and normally situated. The ligamenta lata were still somewhat infiltrated. Although a double-sided pyosalpinx existed, the tubes and ovaries could be distinctly made out, and the local condition was relatively painless. The general condition of the patient was astonishing, her color pink, her appetite good, and her subjective condition splendid. Six weeks later her condition remained absolutely unchanged. I then began the treatment of twenty patients, all selected cases. No patient was treated without rest in bed for a week previous to the baths, to determine what influence rest alone exerted. The baths were begun at a temperature of 27° R., lasting eight minutes, and contained half the strength of CO_2 contained in a Sprudel bath. The temperature of the water was lowered on succeeding days, no bath being given lower than 22° R., the amount of CO_2 being increased with the lower temperatures. Baths were given on three successive days, with a rest of one day before the next three baths. During menstruation no treatment was given, so that in four weeks the patients had on an average eighteen baths each. All remained in the clinic, and no change was made in the way of diet. In all cases an effect was noted in the first few days, first in the condition of exhilaration after the bath, in the increase in diuresis and the increase in appetite, and then decidedly in a feeling of well-being and confidence in the method. Locally examination showed a fulness of the parts, and a distention of the ligaments and cellular structures with a decided element of elasticity. The cases examined every other day disclosed a most rapid resorption of exudates and infiltrations, and a decided diminution in the size of the adnex tumors. As it is my purpose later on to discuss these and future cases more in detail, I will say that the majority were cases of pyosalpinx with severe symptoms. With the exception of one case diagnosed as hydrosalpinx, the remainder belonged to the class I have termed hysteroptosis. In the first-mentioned class it was difficult to define distinctly at first the tubes and the ovaries on account of the accompanying inflammation and congestion of the parametrium. It was astonishing how gradually this element disappeared, so that at the completion of a treatment the tubes in nearly every case were made out to be scarcely of the thickness of the thumb, and the ovary could usually be well defined. One case of a very chronic character was decidedly bettered so far as resorption was concerned, but on account of the pain the patient insisted on operation, although only nine baths had been given. Double salpingectomy was performed, and I found the adhesions so congested, œdematous, so soft and so easily loosened, and the infiltration of the parametrium so slight, that I consider this improvement, a result of the baths, to have been a valuable preliminary to operation. The amount of pus was not large, and I gained the impression that bath treatment longer continued would have freed the patient from her annoyances. I feel certain that, within an interval of three or four weeks between a course of baths, in a series of three treatments she would have been practically cured. We know that salpingitis and pyosalpinx are not incurable affections. It is necessary to distinguish those cases due to gonococci, in which the inflammation follows usually the course of the mucous membrane of the uterus and tube, and those cases due to streptococci and staphylococci, in which the inflammation follows the course of the blood and lymph channels. In the first class, the peritoneal affection is a result of the pus accumulation in the tubes. In the second, the pyogenic affection of the tubes is usually the result of the peritoneal exudation. Since these so-called septic cases rarely give the large pus tubes found as a result of gonorrhœal infections, we may say that in the septic cases the peri-

toneal affection is the primary, while in gonorrhœal cases we are dealing with an affection of the adnexa. And yet in all probability the important factor in the causation of the severe symptoms associated with both these classes of inflammations of the adnexa is to be found in the resulting peritoneal adhesions, and the involvement in the adhesions of the omentum and the intestine. That already formed adhesions can be resorbed, and further adhesions prevented and the organization of the adhesions avoided by these baths, I believe to be well grounded theoretically, and to be proven practically.

Since in the early stages of pelvic inflammations and pus formations in women the involvement of the parametrium is an important factor, and since these baths exert such a decided influence on parametric and perimetric inflammations, I consider the use of these baths after acute inflammations decidedly indicated. Two cases of febrile purulent parametritis were relieved by vaginal incision, and subsequent treatment by the baths proved their resorptive powers beyond question. One case of double-sided pyosalpinx was treated with a bath two days after a return to normal temperature. After the first bath the patient suffered an acute exacerbation, with posterior purulent parametritis, subsequently treated by vaginal incision. I doubt that the bath was a factor in the causation of this attack, yet I believe it to be unwise to begin this treatment until the temperature has remained normal several days. The case of hydrosalpinx showed a return to normal size after ten baths, and seen four weeks later showed no sign of distention.

In the later stages of these pelvic inflammations, the seat of the trouble is localized mainly in the adnexa, and I believe that these conditions, even though chronic, may be cured by this method of hydrotherapy. Though the prospects in gonorrhœal cases are not so good as in the septic, Kustner favoring conservative treatment says: "Gonorrhœal processes, even when they have caused decided distention of the tubes or large palpable exudations, are often open to cure. Such a cure is often followed by sterility as a result of permanent changes of the mucous lining of the tubes. At times, however, their function is restored." Schauta finds in the presence of pus, even without severe symptoms, an indication for radical operation. His view is shared by many, although evidence is furnished of many cases in which under such conditions after conservative treatment pregnancy occurred. Küstner's opinion is expressed by Herrmann, who says: "(1) A certain per cent. of adnex tumors can be cured without operation to such an extent that the function of the tubes is not impaired; (2) even when accumulations of pus in the tubes is proved by puncture recovery with possession of function is possible; (3) in adnex affections which demand operative interference the retained healthy or only slightly diseased adnexa of the one side can later functionate normally." Since Kiefer, Wertheim, and others have shown that within a year after infection the pus is sterile, Herrmann pleads for the conservative treatment of these cases on these grounds: "(1) These cases not infrequently are restored to a normal condition; (2) in this limit of one year, within which conservative treatment should be tried, the pus becomes sterile; (3) if operation must later be performed, it can then be done abdominally without danger of infection, a method which permits of the retention of the uterus and probably of an ovary or ovarian rests; (4) such retention of these parts spares the patient the annoying symptoms following radical operation." Without at this time dilating upon the indications for and against radical operation, or for or against the abdominal method, it is sufficient to say that such reasons are decidedly legitimate and demand at least a trial of conservative methods. Since at least one-half of the cases of pyosalpinx operated upon are found to contain sterile pus, these cases as well as the others, if not operated at once after infection, furnish us practically with smaller or larger encapsulated sterile abscesses, and the problem which confronts us is the possibility of their resorption, and the resorption of the infiltrated inflammation of the tube walls. Since in none of my cases was there a failure of resorption of the exudations about the tubes, and since in no case did examinations show the tube finally to be more than finger thick, and since in most of these cases the ovary could, on examination, be distinctly felt and separated from the tube, I consider that a resorption of the tube contents and a decided influence upon its mucous lining are possible. It is certain that the diminution in the pain, both subjective and that experienced on examination, was diminished to such an extent that a resorption and a loosening of adhesions must likewise be taken for granted.

Those cases called hysteroptosis were decidedly benefited. All the patient gained in weight and strength, and the number of red blood cells was constantly increased. Appetite improved, and a feeling of strength and exhilaration resulted, such as no other treatment in my opinion could have accomplished in the same time. At the same time the local symptoms, and, what is more important, the idea that a diseased local state existed, disappeared. One case of oöphoritis was in no wise locally or generally improved. It belonged to the class of ovarian affections presenting anatomical changes, probably cystic, with a tense tunica fibrosa, in which no beneficial local improvement was expected by me.

I believe that the results obtained justify me in claiming for the carbonated saline baths a power of resorption too valuable to be underestimated, a method which at the same time benefits the general state to a decided degree, and which acts by increasing the natural and effective functions of the body, and in toning up those pelvic structures which depend so decidedly for their elasticity and blood supply on the condition of the body generally.

A SIMPLE METHOD FOR WRITING PRESCRIPTIONS FOR CHILDREN.

By MAX HUHNER, M.D.,

ATTENDING SURGEON BELLEVUE HOSPITAL, OUT-PATIENT DEPARTMENT.

As is well known, the method of calculating the dose for a child is, according to Cowling's Rule: age at next birthday, divided by twenty-four. A simple method for writing the prescription, in order to avoid much calculation, is to make it contain exactly twenty-four doses, whence it necessarily follows that the entire amount of any drug in the prescription will be the adult dose multiplied by the age at next birthday. Let us for example take three drugs *x*, *y*, and *z*, of which the adult dose of *x* is ℥ v., of *y* ℥ viii., and of *z* ℥ x. We write our prescription as follows:

℞ *x* .....
y .....
z .....
Aq. .....q.s. ad etc.

Now if we make the entire quantity ℥ iii. and the amount taken at each dose ℈ i., our prescription will contain twenty-four doses, thus:

℞ *x* .....
y .....
z .....
Aq. .....q.s. ad ℥ iij.
M. S. ℈ i. t.i.d.

If the child at its next birthday is one year old, our

prescription is completed by simply putting the adult dose after each item, thus:

For baby F——, aged one year.

℞ *x* ..... ℥ v.
y ..... ℥ viij.
z ..... ℥ x.
Aq ..... q.s. ad ℥ iij.
M. S. ℥ i. t.i.d.

If three years old, simply put down three times the adult dose, thus:

For Baby F——, aged three years.

℞ *x* ..... ℥ xv
y ..... ℥ xxiv.
z ..... ℥ xxx.
Aq ..... q s. ad ℥ iij.
M. S. ℥ i. t.i.d.

If ten years old, put down ten times the adult dose, thus:

For Baby F——, aged ten years.

℞ *x* ..... ℥ l.
y ..... ℥ lxxx.
z ..... ℥ c
Aq ..... q s ad ℥ iij.
M. S. ℥ i. t.i.d.

To exemplify with an ordinary cough mixture:

℞ Syr. ipecac .....
Ammon mur .....
Ex. scillæ fl .....
Aq ..... q.s. ad ℥ iij.
M. S. ℥ i. every three hours.

If the child is one year old (at next birthday) we put down the adult dose after each item, as follows:

℞ Syr ipecac ..... ℥ x
Ammon. mur ..... gr. v.
Ex. scillæ fl ..... ℥ ij.
Aq ..... q.s. ad ℥ iij.
M. S. ℥ i. every three hours.

If six years old, put down six times the adult dose, thus:

For Baby F——, aged six years.

℞ Syr. ipecac ..... ℥ lx.
Ammon. mur ..... gr. xxx
Ex. scillæ fl ..... ℥ xij.
Aq ..... q.s. ad ℥ iij.
M. S. ℥ i. every three hours.

And so forth. The advantage of this method will perhaps be more fully appreciated by giving drugs with fractional doses. Let us for sake of example give a child some pills containing strychnine sulphate and digitalin. We write our prescription as follows:

℞ Strychninæ sulph. .....
Digitalin .....
M. et fiant pil. No. xxiv. S. One pill t.i.d.

If the child is four years old we put down four times the adult dose after each item, thus:

For Baby F——, aged four years.

℞ Strychninæ sulph. ..... gr. $\frac{4}{60}$ = gr. $\frac{1}{15}$
Digitalin ..... gr. $\frac{4}{100}$ = gr. $\frac{1}{25}$
M et fiant pil. No. xxiv. S. One pill t.i.d.

There is absolutely no calculation necessary, as long as we make our prescription contain twenty-four doses. All we need to know is the adult dose of each item, and multiply it by the age of the child, and that will give us the entire amount to be placed after each item. If we do not wish to give as many as twenty-four pills, we may give twelve, and divide each amount by two.

The method may, of course, be used in the metric system, as follows:

For Baby F——.

	For one year.	For four years.
℞ Strychninæ sulph.	0.001	0.004
Digitalin.	0.0006	0.0024

M. et fiant pil. No. xxiv. S. One pill t.i.d.

Another slight advantage is, that we may give the same drugs to several children of a family without writing different prescriptions. Thus in the first example (the cough mixture) we may give the same prescription for three children, aged respectively one, three, and five years (at next birthday), by telling the mother to give one child ℥ i., another ℥ iii., and the oldest ℥ v. at each dose.

As this method depends upon Cowling's Rule, it is applicable only where Cowling's Rule is applicable. In giving opiates, etc., where less than $\frac{1}{24}$ of adult dose is given, we cannot, of course, make use of this method.

The fact that the dose for a child should be regulated not by its age, but by its physical development does not militate against the use of this method; for if a child of three years has the development of a child of five years, it may, for purposes of dosage, be considered a five-year-old child, and the prescription calculated accordingly.

358 East One Hundred and Twenty-first Street.

A METHOD FOR THE DETERMINATION OF EYE DEFECTS IN SCHOOL CHILDREN, WITH A REPORT OF SEVENTEEN HUNDRED AND FORTY-SEVEN EXAMINATIONS.

By LOUIS C. DEANE, M.D.,
San Francisco,
Surgeon to the California Eye and Ear Hospital, etc.

The object of this class of work is to determine the ocular defects existing among school children. The public can be divided practically into two classes, those who have good and useful eyesight and those whose sight or condition of the eyes is so poor as to incapacitate them for their daily pursuits. The large number of examinations that have to be made, and the rapidity with which the oculist is compelled to complete them, so as not materially to interfere with the school work, compel him to overlook a considerable number of minor eye defects, which he can only suspect but not investigate; for instance, to discriminate between a low grade of myopia and astigmatism, whether there exists a small amount of plus or minus astigmatism, or even higher grades of astigmatism at irregular angles.

Time does not admit of an ophthalmoscopic examination, hence many pathological changes in the fundus of the eye must be overlooked. If the sight is poor and the patient refuses to show symptoms of any of the refractive defects, a more thorough examination is necessary at a later period.

The method used I believe to be the most complete and thorough within the bounds of practice, and by it one is enabled to examine between twenty and thirty pupils hourly, or between fifty and sixty eyes.

Another point to be considered is the age and advancement of the pupil. As children progress in their studies and are compelled to concentrate their eyes more closely, they develop defects which do not trouble younger ones.

As age increases, the range and flexibility of accommodation decreases, and refractive ocular defects, which tax the accommodative powers, are more difficult to overcome. This incapacity is manifested by headaches, blurring of print, inflamed lids, watery eyes, etc. The statistics with regard to the younger ones of between six and ten years cannot be accurate, since the judgment of the scholar in regard to what he sees and how he sees it has to be relied on. The careful observer will always detect any marked error of refraction, with defective eyesight, heterophoria, strabismus, or diseases of the lids. Any objective method, as retinoscopy, is impracticable.

The teacher of each class is directed to arrange in a column alphabetically the names of her pupils, their age and sex, leaving a space after each one for the result of the examination. A copy of this is returned to the teacher with an explanation, so that she is cognizant of the visual acuity and condition of the eyes of each of her pupils. This is of twofold importance: first, it allows the teacher to seat the pupils with relation to distance from the blackboard for those with poor vision, and the intensity of light for those with weak eyes, also to favor those who are suffering with an unconquerable eye-strain. Secondly, these reports should be kept on file so as to be of future value to the oculist in his examination, and allow him to elucidate many important facts which can be accomplished only by reference to numerous personal records extending over some years. The bulk of such a work would fall on the first year, as in the succeeding years, by reference to previous records, most pupils could be excused from a repetition of the examination, and the suspected ones re-examined as to the progressiveness of their condition. It is unnecessary to repeat here the value of such records, not only to regulate and correct eye defects during the school term, but to advise the parents as to the care and future pursuits of their children.

During the school hours the children are allowed to leave the class five at a time and adjourn to a separate room, twenty feet long, with good light, provided for the purpose.

It would be well to stop here and note the appliances necessary to continue this examination: Five ordinary test charts with radiating lines for astigmatism. Spectacle fronts containing pairs of the following spheres: + .75 D., + 1. D., + 1.50 D., — .50 D., — 1.50 D., — 2.50, and cylinders + .75 D. ax. 90°, + .75 D. ax. 180°, — .75 D. ax. 90° and — .75 D. ax. 180°; also prisms 6° base in each eye, 2° prism base down on one eye and 3° base up on the other eye. A red glass.

The children are directed to stand in line and cover their left eyes with their left hands, using the palm not the fingers, and keeping both eyes open. The first is directed to read the $\frac{20}{50}$ line on chart 1; if he reads the line, the next is directed to read a similar line on chart 2, and so on through the five. If the vision is $\frac{20}{60}$ no record is made; if not it is recorded thus: R. V. $\frac{20}{40}$, or whatever the sight may be, following the name. Those who have V. $\frac{20}{30}$ both are tested with + .75 D. sph., and so on to + 1.50 D. sph., noting which one blurs the $\frac{20}{30}$ line. If + .75 D. sph. reduces the visual acuity, I make no note of it, but consider the case emmetropic. If + 1.50 D. sph. is the first glass which blurs the print I consider the case as hypermetropic + 1. D., etc. It is well to note that the maximum amount of relaxation of the ciliary muscles is not obtained thus, so that the manifest amount only is shown, which simply serves as a clew to almost any amount of the absolute condition. One thing is certain (providing the judgment of the scholar can be depended on)—that there is a hypermetropia present, and more than is manifested at the time. Minus lenses can be used for those who show a defective vision, and the strength of the weakest noted, as also the cylinders.

The screen test is used to determine the muscular balance of the eyes, and is most practical. By it as little as 2° of an esophoria is easily noted. If a further investigation is desired the prisms in the spectacle fronts are provided for that purpose, producing a horizontal or vertical diplopia, which are used here to show more the kind than the amount of heterophoria; though the latter can be easily estimated, if desired, by a chart at a distance of twenty feet, divided off to show the deviation produced by certain prisms and consequently the approximate amount of a heterophoria. If a state of orthophoria exists no note is made, and the examination is continued, taking note of corneal opacities, blepharitis, conjunctivitis, etc.

The majority of those examined are immediately returned to the class room, those who manifest some marked defect being detained for a further examination, possibly of each eye separately with the test glasses for an anisometropia, etc. It is well to examine the less fortunate ones alone, as children in schools are very sensitive as to imperfect eyesight, and, with others present, their answers are often misleading.

In the foregoing one is impressed with the fact that the examination is merely qualitative and not quantitative. Records are made only of conditions with but approximate measurements.

What are we to find in this examination, and what are the value of such findings?

1. Elimination of those with normal eyesight without apparent ciliary strain or muscular imbalance of the two eyes.

2. Hypermetropia with or without asthenopic symptoms.

3. Myopia, percentage in the different grades of school, its progressiveness with and without the use of glasses.

4. Astigmatism: this is difficult to determine by these tests, but if the vision remains poor, and the error cannot be accredited to a myopia, a further examination is necessary also.

5. Poor vision which cannot be accounted for by a refractive error.

6. The relation of ametropia to heterophoria or heterotropia, showing the relation of hypermetropia to esophoria, and esotropia and myopia to exophoria and exotropia.

7. Relation of marginal blepharitis, chronic conjunctivitis with styes, phlyctenular conjunctivitis, etc., to ametropic conditions, especially to hypermetropia.

Following is a report of the examination of 1,747 school children, of which 421 were boys and girls in the high school, where I was able to carry out the examination with considerable accuracy. The remaining 1,326 were taken from the higher grammar grades, where the results were also fairly satisfactory. The appended table was made up at a later period from the reports given the teachers. On account of inadequate space, I have somewhat condensed it, having omitted acuity of vision, which was arranged in four columns as follows: V. $\frac{20}{30}$ to $\frac{20}{40}$, $\frac{20}{50}$ to $\frac{20}{70}$, $\frac{20}{80}$ to $\frac{20}{100}$, and worse than $\frac{20}{100}$ for the fourth column. If the vision was normal on record was made, if both eyes were defective the vision of the best was recorded, which shows the practical vision of the child with both eyes open. Two columns for anisometropia were also omitted, the vision of the worst eye being recorded thus, $\frac{20}{40}$ to $\frac{20}{60}$, and the other column for vision worse than $\frac{20}{60}$. The vision of the best eye had already been recorded under acuity of vision.

	Number of Examinations.	Average Age.	Marginal Blepharitis	Heterophoria.		Heterotropia.		Vision $\frac{20}{30}$.	Anisometropia.	Hypermetropia.	Myopia.	Poor Vision Undetermined.

It will be noted that marginal blepharitis is less

frequent in the older pupils; this may be due to two causes: first, the percentage wearing correcting lenses for hypermetropia is much greater; second, they are more likely to have been treated. Certainly many mild cases were overlooked, only the marked and noticable ones being recorded.

The increase of heterophoria as the scholar progresses is due, I believe, to the fact that more is manifest, *i.e.*, he is less able to overcome such defects.

Hypermetropia remained about the same, but many more were wearing correcting lenses in the high school than in the grammar, especially among the boys.

The table shows a large percentage of myopia in the high school, especially among the girls; many of the latter were without glasses on account of prejudice against them, while most of the boys were wearing their proper corrections. This may account in a way for a greater frequency of myopia among the girls. I noted that in the classical courses, especially in the Greek senior classes, the percentage of myopia was alarming. In one class of 38 pupils, 16 had over 1.50 D. of myopia, or 42 per cent.

In the column of poor vision undetermined were cases in which an ophthalmoscopic examination would be likely to have revealed the cause in a possible very high myopia, astigmatism, fundus disease, or opacity of some of the transparent refractive media.

Of the 6 cases of strabismus observed in the high school, 5 were divergent and 1 convergent. Of the divergent, 4 were myopic and 1 hypermetropic; 2 were anisometropic and 3 isometropic. The one case of convergent strabismus was hypermetropic and anisometropic.

Of the 7 cases of marginal blepharitis observed in the high school, 4 were hypermetropic, two myopic, and 1 emmetropic.

The relations between heterophoria and ametropia were particularly interesting. Of the 37 cases of heterophoria over 3° found in 421 pupils examined in the high school, 5 had esophoria and 32 exophoria. Of the 5 cases of esophoria all were hypermetropic. Of the 32 cases of exophoria, 15 were myopic, 2 hypermetropic, and 15 emmetropic.

606 Sutter Street.

The Operative Treatment of Procidentia Uteri in Elderly Women.—A. Lapthorn Smith says that in the majority of these cases we find a lacerated cervix, and that this together with a lacerated perineum forms the initial lesions, which brings about the prolapse. The laceration prevents involution of the uterus, and the latter organ, instead of becoming small and light, remains large and heavy. Owing to the too general practice of keeping women lying on their backs after confinement, the subinvoluted uterus becomes a retroverted one by gravity, and when the woman gets up the bowels fall in front of the womb, and the round ligaments are unable to pull the fundus forward again, so that the uterus is forced on to a lower plane in the pelvis. There being no perineal support to oppose both gravity and intra-abdominal pressure, the cervix appears at the vulva, bringing the bladder and rectum with it, causing a chronic cystitis and a dragging pain in the back. In regard to operative measures we may follow one of two plans, according to the degree of the prolapse and the size of the uterus. If the latter is small and not far enough out of the body to become ulcerated, the safest operation is to make a small incision in the abdomen, and catching the fundus with the bullet forceps, draw it up to the incision and scarify the whole anterior surface of the fundus, and then to sew it to the abdominal wall with buried chromicized catgut; after which the vaginal outlet is narrowed by a large anterior and posterior colporrhaphy. If, however, the uterus is very long, sometimes the sound measures seven or eight inches deep, and especially if it is badly ulcerated, it is better to amputate all but the upper two inches of it, and then to narrow the outlet.—*Canadian Practitioner and Review*, October, 1900.

The Psychical Influences Acting on Patients in Sanatoria.—These have been found by P. Wiedeburg to be both favorable and unfavorable, and to be of great importance in facilitating or impeding the work of successful treatment. Most of them depend directly or indirectly on the tact and general attitude of the physician in charge, who, by attention to apparently minor details, can to a remarkable degree enhance the value of the primary therapeutic measures employed. The work of psychical influence or suggestion begins even before admission, for the idea of treatment in an institution is usually of itself enough in some cases to put the patient in a more hopeful frame of mind, while in others it has precisely the opposite effect. It is highly important that the patients should be inmates of the establishment itself, and not board outside and come there merely for treatment; for the disciplined life under the personal supervision of the physician, who should make it a point to meet his charges frequently outside the consulting-room as well as in it, removes the risk of many indiscretions in the way of diet, exertion, etc., to which they would otherwise be exposed. The social life among the patients must be subjected to careful supervision; while the encouragement of association with a cheerful and hopeful fellow-invalid can be of inestimable service, depressing companionship may do untold mischief. The providing of interesting amusements, attention to the table, strict management of the employees attending to the service and performing the functions of masseurs, orderlies, etc., and the control of visits, correspondence, and reading-matter are all of great import in determining the psychical state of the patient, and his consequent susceptibility to the remedial measures employed.—*Zeitschrift f. diätetische und physikalische Therapie*, vol. iv., No. 5, 1900.

Syphilitic Sciatica.—In a general article on this subject, J. K. Baudy enumerates the following rules concerning diagnosis. 1. In making the diagnosis of syphilitic sciatica, it is necessary in the first place to establish the fact that, in addition to having neuralgic pain of the sciatic nerve, the patient has previously had syphilis. It should not be forgotten that the fact of sciatica occurring in a syphilitic patient does not warrant the assumption that the nervous complaint is necessarily due to constitutional syphilis. 2. If the patient has been free from sciatica previous to syphilitic affection, this fact will weigh in favor of the supposition that the neuralgia is of syphilitic origin. 3. While syphilitic sciatica may occur at an early period of infection, it is more likely to occur later. 4. The occurrence coincidently with the sciatica of other neurotic troubles, clearly traceable to syphilis as a cause, constitutes a presumption in favor of the syphilitic origin of the sciatica, and this presumption will be strengthened if the patient had previous to constitutional infection been free from both sciatica and the other neurotic infections. 5. The pains of sciatic neuritis are dull, continuous or nearly so, and persistent; also are felt equally throughout the whole course of the sciatic nerve, thus offering a marked contrast to the lancinating pains of a pure sciatica, which are chiefly felt at the extremities of the nerve. 6. In sciatic neuritis, again, the nerve is tender to touch, and can often be felt as a thickened cord beneath the skin.—*St. Louis Medical Review*, September 29, 1900.

MEDICAL RECORD:

PROGNOSIS IN TYPHOID.

THE importance of making an accurate prognosis in any given case of typhoid fever is very effectually offset by the absolute uncertainty of foretelling the time and nature of always threatening complications. The question from this point of view has an added interest in connection with the sickness of the Czar of Russia, on the ultimate issue of which so much political significance depends. From all accounts the fever is in its second week, with a comparatively easy temperature grade, a reasonably quiet pulse, and no marked feeling of prostration. Apparently then the patient is making a good start, with mild symptoms. Every one knows, however, that such signs are not always trustworthy as guaranteeing against future dangers. While very high temperatures in the beginning of the attack generally indicate the degree and gravity of the poison, it by no means follows that a contrary condition can insure the patient against complications which have nothing directly to do with the degree of infection. The "walking cases," for instance, are particularly prolific with accidents of intestinal hemorrhage and perforation, are peculiarly liable to auto-infection and relapse, and in a general way balance the chances of a good beginning with a bad ending on the usual compensatory level.

We must admit of course that the vital resistance of individuals is a very powerful determining element as to the impression of the poison, and also its early elimination. It is a matter, so to speak, of dead reckoning how much poison is absorbed in a given case and how quickly and effectually it can be thrown off with a minimum amount of harm to the patient. Apparent robustness has seemingly nothing special to do with this phase of the calculation, inasmuch as thin and apparently weakly subjects astonish us by their endurance, prompt responsiveness to remedies, and by their staying-powers during convalescence.

A favorable indication of satisfactory progress is the steady and regular course of the temperature curve: the morning and evening alternations, the gradual rise to the top wave, and then the decline to the level of convalescence. In the same way the pulse must match its quickened throb with the increased heat of the tissue fire and mark its own rise and fall on parallel lines. Thus the consistency of satisfactory progress is made possible, and the fever takes its course through all the usual presentments of accident. We trust everything in prognostication to the integrity of the machinery and its ability to bear the necessary strain. The careful physician is content to say that under the circumstances the patient is doing well for the time being. If he attempts to look too far ahead he must needs only guess and qualify.

What holds good as to positiveness in regard to the exact duration of fever, and its possible complications, applies with equal force to the behavior of the convalescence stage. Often the latter is more trying to patient and physician than the original ailment. Here also there is no law that can govern opinion as to the precise day when the temperature shall become normal and remain so. Often during a calm of symptoms there is an ominous and threatening afterclap of high temperature and increased pulse rate. Indeed, after such profound systemic disturbances as have existed for weeks it takes time and adjustment to get to the even and quiet level of established health. But how to mark the exact time limits along the line must always be the puzzle so long as one patient differs from another in receptivity, reaction, and vital power.

THE PREVENTION OF INSANITY.

ONE who follows current medical literature cannot but be struck by the frequency—the increasing frequency—with which questions of prophylaxis are discussed. This is rather in striking contrast with the criticism that has been made, more especially in connection with diseases of the nervous system, that only a small minority of papers written deal with questions of treatment—and it is worthy of note that not a few of the discussions in preventive medicine relate more particularly to diseases of the nervous system. The circumstance in question is obviously referable to increased knowledge of the etiology of disease, and it is to be anticipated that further advances in prophylactic measures must follow upon the same lines. The truth, with regard to matters of health and disease, is viewed with much less sentimentality now than it was formerly, and the importance of hereditary influences in the transmission of morbid tendencies is receiving increasing recognition. More especially is it being appreciated that mental and nervous diseases are not in themselves to be considered causes for shame that call for concealment; but rather that they should be early and unreservedly brought to the attention of the physician, in order that such steps as are available may be taken in the cure, as well as in the prevention of hereditary transmission, while, as already indicated, a full knowledge of the etiological factors will permit of the recommendation of measures of primary prophylaxis. This is the spirit that pervades the introductory address of the president of the section of psychology at the recent meeting of the British Medical Association.[1]

It is pointed out in this communication that there has been not only an absolute, but also a relative, increase in insanity in England and Wales in recent

[1] "The Prevention of Insanity," by R. Percy Smith, M.D., F.R.C.P. Lond. Lancet, August 11, 1900, p. 388.

years, so that there is ample justification for efforts "to diminish, if possible, at the source the numbers of those who thus become incapacitated either temporarily or permanently, who, if not possessing private means, become either a burden to their relatives or to the tax-payer, and who in some cases become criminals as the result of their mental disorder." Attention is devoted to three subjects: (1) The propagation of the race by those of insane inheritance or those who have suffered from insanity; (2) the influence of alcohol in the production of insanity, and the need for preventive legislation; and (3) the causation of general paralysis by syphilis.

Heredity is found to be an etiological factor of insanity in not less than from twenty to twenty-five per cent. of cases—a larger proportion than is associated with any other single cause. For the future welfare of the race and the maintenance of its stock in as healthy a condition as possible, reproduction from defective individuals should not be permitted. It is true that great and practical advances have been made in the care and treatment of the insane, but there is urgent need for the imposition of restraint in the marriage of members of families in which insanity exists or has existed. The danger is, of course, greater when the taint affects both contracting parties and also when consanguinity exists. Remedial or restrictive legislation can scarcely be expected, and, even if enacted, it would be more commonly honored in the breach than in the observance, so that upon the medical man will devolve the responsibility of effectuating so much of the reform in this direction as can be brought about. His, also, will be the duty of educating the community as to the dangers that reside in marriages among the progeny of insane parents or those that themselves are or have been insane. Such unions must be looked upon as nothing less than social crime. So common has become the proposition that defectives should be deprived of the power of propagating their kind, that there is increasing reason to hope that the day is not distant when the suggestion shall be put into practical effect.

Next to heredity, alcohol is the most potent single cause of insanity, from nine to twenty-two per cent. of cases being attributed to its influence directly, apart from any effect it may have on the progeny, and not including cases of acute alcoholism. In addition, it has been found that there is an intimate relationship between alcoholism and suicide. The remedy consists in arrest for simple drunkenness, punishment for serving habitual drunkards with alcohol, and affording protection to the family of the victim.

It is almost universally admitted that syphilis is the most prolific, if not the sole, etiological factor of paretic dementia, which in hospitals for the insane is one of the most common causes of death, especially among men in the prime of life. Paretic dementia is most common where syphilis, alcoholic influences, and dissipated methods of living are most prevalent, and in addition to training individuals in habits of self-control, and teaching them to observe physiological laws, legislation might be enacted to check the spread of such a potent poison to the nervous system as syphilis. It is suggested that the disease should be made notifiable. In Finland, where physicians are required to notify the medical officer of health of the existence of any case of venereal disease, without giving the name of the patient, where opportunities for hospital treatment are afforded, and the authorities have the power to compel the examination of any suspected individual, the prevalence of syphilis has been greatly diminished in the past twenty years, congenital syphilis has become less frequent, and the type of both the hereditary and acquired forms has become much milder. Punishment has been proposed for those who, knowing themselves to be infected, put themselves in the way of infecting others.

THE HEALTH OF NEW YORK.

Dr. Henry Dwight Chapin, chairman of the committee on hygiene of the Medical Society of the County of New York, has lately published his annual report regarding the health of New York City. It is gratifying to gather from Dr. Chapin's investigations—the data of which were gleaned from the exhaustive study of the question made by the Merchants' Association of New York—that the health of New York compares favorably with that of the six largest capital cities of the world. Berlin has the lowest death rate and St. Petersburg the highest, while the mortality per one thousand of New York and London are the same. However, the fact must be taken into account that the death rates for New York are estimated for the boroughs of Manhattan and the Bronx only. Nevertheless it is a matter for congratulation that there has been a steady decrease in the death rate of New York as a whole during the past few years. Dr. Chapin attributes this to a lessening of the virulency of influenza brought about by the better paving of streets and a more careful oversight of water and milk supply. Further improvement in the quality of the milk supply is anticipated, and with this end in view a committee of the Medical Society of the County of New York has been making a careful study of the question and suggesting practical measures. The greater portion of the report is wisely devoted to a consideration of the water supply, which has of late been attracting the attention of sanitarians and citizens of all classes. It is notorious that the water supply of New York is insufficient for the growing needs of the population, and it is also manifest that steps must be quickly taken to remedy the present state of affairs. Dr. Chapin points out that all of the supply of Manhattan, as well as all of the Bronx, is furnished by the city with the exception of about one million gallons daily, which is furnished by a private company. Brooklyn depends mainly upon ponds and driven wells on Long Island, of which the city owns all but about seven per cent. Queens is supplied by wells, about thirty per cent. owned by the city and the remainder by private corporations. Richmond is supplied by wells on Staten Island, constructed and managed by private enterprise. The average daily consumption of all the boroughs in the city of New York was in 1899, 371,778,-

000 gallons, an estimated average daily consumption per capita of 103 gallons. The Croton watershed when completed is expected to yield from 278,000,000 to 280,000,000 gallons per day. From other sources available for the boroughs of the Manhattan and the Bronx from 1,5000,000 to 17,000,000 gallons are obtainable, making in all for these boroughs about 290,000,000 gallons per day. The investigation by the engineering committee of the Merchants' Association shows that in Brooklyn, Queens, and Richmond the present consumption nearly equals the present supply; that in Manhattan and the Bronx the consumption in 1903 will nearly equal the supply at that time available under present methods. Therefore it is perfectly evident that vigorous measures should be initiated at once to enlarge the present water supply, and to introduce reforms into the existing mode of managing the same. As Dr. Chapin ably presents the situation, "From six to seven and one-half years will be necessary from the inception of the work to the delivery of additional water, and immediate steps should be taken to furnish an adequate supply of water, to be available at the latest in 1910." The space at our disposal is too limited to discuss at length the result of the investigations carried out by the engineers of the Merchants' Association. They believe that the Hudson River above Poughkeepsie should be utilized as the main source of water supply for New York, and contend that by an efficient system of filtration such water can be rendered excellent for all domestic purposes. This is undoubtedly the case, and has been conclusively proved in London and in many large American and European cities, where since the adoption of like methods the death rate from zymotic diseases, notably diarrhœa and typhoid, has been immensely decreased. Dr. Chapin concludes his report by entering a strong plea for public ownership of water supplies in New York, in which we heartily concur. The plan has been found to answer admirably in Glasgow, Scotland, and in other centres of population in which it has been given a trial. The cost is much less, and there is not the opportunity—or, at least, there should not be—of making large profits at the expense of the general public as in private ownership. The sanitarians and medical men of New York should use their best efforts to procure a plentiful, pure, and cheap water supply.

THE ETIOLOGY OF YELLOW FEVER.

An amusing illustration of the odium medicum is furnished by the controversy on the subject of the yellow-fever germ now occupying the thoughts and governing the words of certain surgeons of the Marine-Hospital service on one side and of the Army Medical Corps on the other. The former have warmly espoused the hypothesis of the Sanarelli bacillus because they think they have found that germ in the bodies of yellow-fever patients. The latter with some emphasis reject that theory because they have not found the bacillus icteroides in cases of yellow fever, and think they have found it in the cadavers of persons dead of some other disease. We have read with more or less interest the now somewhat voluminous literature put forth by both parties to the dispute, as well as some of that produced by volunteer partisans of one side or the other, and we are obliged to say that we have as yet come across no very convincing testimony advanced by Sanarelli's disciples in support of their leader's assumption.

The dispute has now entered upon a new and to the onlooker a more interesting phase with the adoption by the army and the rejection by the Marine-Hospital service of Finlay's mosquito theory of the spread of yellow fever. The army board, whose inconclusive findings we noted a couple of weeks ago, suggests that the mosquito is the intermediate host of the yellow-fever germ, but Dr. Wasdin, of the Marine-Hospital service, scouts this suggestion, holding that any inoculation of the disease in that way is purely accidental, and he denies that Culex fasciatus or any other mosquito is essential to the spread of yellow fever. Of course the facts adduced by the members of the army board in support of their adopted theory are utterly inadequate, and it is strange that scientific men, such as they undoubtedly are, could bring themselves to put forth seriously any such flimsy evidence. They could have made out a much stronger case by simply republishing Finlay's papers on the same subject. In spite of the lack of proof, however, this fascinating theory may be the correct one, and if it should prove so to be it is not improbable that it will direct us, following out the analogy of the malaria germ, to the discovery of the true cause of yellow fever.

Some time ago Klebs published a paper in which he described certain oval or egg-shaped bodies which he had found in the liver and the mucous membrane of the stomach and duodenum of a man dead of yellow fever. These bodies, which were somewhat larger than a human red blood corpuscle and were found in the tissues surrounded by leucocytes, Klebs believed to be amœbæ, and he suggested that they might prove to be the true parasite of yellow fever. The paper attracted little attention beyond a letter of disapproval from Surgeon-General Sternberg, who said that Councilman had long before observed similar bodies in advanced cases of cirrhosis, in phosphorus poisoning and other cases of rapid fatty degeneration, and especially in acute yellow atrophy. Klebs replied that these appearances were quite different from those seen by him in the organs from a case of yellow fever, but he admitted that the question was one calling for more extensive investigations both in the cadaver and in the living yellow-fever patient. There the matter rested, and the alleged discovery of the Chicago pathologist seemed to have gone to the limbo of unsupported and unpopular medical hypotheses. If Finlay's theory becomes established, however, we may find that the germ which the insect harbors is an amœba, and that it has a separate life cycle in the body of Culex just as the plasmodium of malaria has in that of Anopheles. And then, may be, the warring surgeons will bury the hatchet at the feet of Klebs.

Grippe is reported to be quite prevalent in London.

News of the Week.

A Reception to Dr. William Osler, of the Johns Hopkins University and Hospital, was tendered on November 15th by the Faculty Club of the University of Pennsylvania.

The Plague is raging on the island of Mauritius, where fifty new cases occurred during the first week in November. The deaths were thirty-five. In Alexandria, Egypt, two new cases were reported on November 13th. The disease has also broken out among the natives near King William's Town, twenty-eight miles northwest of East London, Cape Colony. Three deaths have already occurred.

Dr. Angelo Bellinzaghi, who is reported in the papers to have received from the Mexican government an award of $50,000 for the production of a really curative serum for yellow fever, is said to be on his way to New York and Washington. He announces that he is about to organize a company, with a farm near San Antonio, Texas, for the production of his serum on a large scale. Dr. Bellinzaghi seems not to have published his method of preparing the serum, nor have we seen in any medical journal any account of his bacteriological studies of yellow fever, if he has made any such.

A Typhoid-Stricken Town.—It is stated in *The Sun* that typhoid fever has become epidemic in Cementon, a town on the Lehigh River, not far from Allentown, Pa. Out of two hundred families composing the population, there are one or more cases in one hundred and eighteen families. Of twenty-two families, all members from the father down to the youngest child are prostrated by the disease, which has now been raging two weeks. There have been several deaths. The water used by the inhabitants of the town is drawn from the Lehigh River, which is very low, owing to the prolonged drought, and is contaminated with the sewage and cess-pool leakage of the towns above Cementon.

Philadelphia Pediatric Society.—At a stated meeting held November 13th Dr. David Riesman presented "A Case of Complete Motor Aphasia in a Child of Eleven Years, the Result of Infantile Cerebral Palsy." There had been difficulty in the birth of the child, probably with the occurrence of meningeal hemorrhage, which had destroyed the speech mechanism in both cerebral hemispheres. Dr. Alfred Stengel reported "A Case of Meningitis"; also "A Case of Osteoarthritis, with Skiagraphs"; and also "A Case of Œsophageal Stricture, with Skiagraphs." Dr. J. P. Crozer Griffith presented "A Case of Possible Cerebellar Tumor." Dr. A. Van Harlingen presented a communication entitled "A Case of Pemphigus, with Some Remarks on the Treatment of this Condition."

College of Physicians of Philadelphia, Section on General Medicine.—At a stated meeting held November 12th Dr. Thomas C. Ely read a paper entitled "Diabetes Mellitus as a Cellular Fault." Dr. David Riesman read a paper entitled "Abscess of the Liver; Hepatotomy; Recovery." Exploratory puncture had evacuated considerable sterile pus, and the operation yielded a like result. Dr. James Tyson read a paper entitled "A Physician's Holiday at Carlsbad." Dr. F. A. Packard presented a specimen of carcinoma of the rectum associated with the lesions of chronic colitis.

Philadelphia Hospital.—The Bureau of Charities has elected a dental staff constituted as follows: Dr. R. H. Nones, Dr. M. H. Cryer, Dr. J. Norman Brownell, and Dr. Thomas C. Stellwagen, Jr. It is proposed to form also a pediatric staff.

Philadelphia County Medical Society.—At a stated meeting held November 14th Dr. Herman M. Biggs, pathologist and director of the bacteriological laboratory of the New York department of health, read by invitation a paper entitled "The Registration of Tuberculosis," in which, after considering the objections that have been made against this practice, he presented a logical and dispassionate argument in its favor, and he related the results of its operation in New York City. For properly dealing with cases of tuberculosis it was contended that the sanitary supervision in every municipality should comprise: 1, compulsory notification; 2, suitable plans for the education of the people; 3, a complete and efficient scheme for the disinfection or renovation of premises vacated by death or removal; 4, a hospital equipment; 5, the power of compulsory removal and detention of patients in a hospital when necessary, in the same manner as is practised in the contagious diseases. He showed that since 1886 there had been a reduction in the mortality from tuberculous diseases in New York City of more than thirty-five per cent., and he expressed the opinion, that, with a complete and efficient scheme for dealing with pulmonary tuberculosis, including suitable hospital accommodations and the proper enforcement of precautionary measures, the death rate from tuberculous diseases in New York City might be further reduced at least one-third within a period of five years. This would mean the saving of three thousand lives annually. After extended discussion, participated in by Drs. J. C. Wilson, A. C. Abbott, A. V. Meigs, J. M. Anders, L. Ott, L. F. Flick, W. M. Angney, M. Woods, S. Flexner, J. Solis-Cohen, A. Stengel, W. M. L. Coplin, and G. Hinsdale, a resolution was adopted recommending to the bureau of health the compulsory registration of cases of tuberculosis, with the adoption of measures looking to the restriction of the disease.

Return of a Disgraced "Ambulance" Corps.—Thirty-three members of the Chicago Irish-American Ambulance Corps, which left this city to help the Boers in the Transvaal last February, got back Saturday on the steamship *Trave*. There were fifty-eight men in the corps, among them six physicians. They were Drs. J. R. McNamara, Herbert McAuley, James J. Slattery, R. L. Long, A. F. Corney, and J. B. Aderholt, all of Chicago. George Cassidy went as a nurse. The other fifty-one were supposed to be litter men.

Before leaving this country each of the fifty-eight men went before a justice of the peace and made affidavit that he was going to South Africa, not as an ally of the Boers but as an ambulance man, and each man pledged himself not to fight. Miss Clara Barton gave the Irish-American Corps a Red Cross flag and recognized the organization as a Red Cross auxiliary. The six physicians and the nurse adhered to their pledges, but all the others entered the fighting ranks of the Boers the minute they reached the Transvaal. Some of the men were killed, some were captured or ran away, and some are still fighting. We are pleased to note that the reception the returning band of pledge breakers got from the committee which had been appointed to meet them was far from cordial, and instead of congratulations they received reproaches for having perjured themselves.

Fire at Cornell University.—The main building of the Veterinary College at Cornell University was damaged by fire on November 13th, about $10,000 worth of laboratory apparatus being destroyed. The total loss was about $30,000.

Yellow Fever in Havana is diminishing since the appearance of cooler weather. At the middle of this month there were sixty-five cases under treatment in the city, seven of them being in Americans. There have been two cases at Natchez and one at Brookhaven, Miss.

Fire in the Hudson Street House of Relief.—A fire did slight damage to the Hudson Street Hospital on Friday morning of last week. It started in the laundry on the top floor, but was extinguished quickly without disturbing any of the thirty-five patients at the time in the wards. The hospital is the accident branch of the New York Hospital.

University of Michigan's Homœopathic Hospital.—The new Homœopathic Hospital of the University of Michigan was opened on November 15th and filled with patients formerly cared for in part of the University Hospital. The formal opening will take place in the first week of December. Dr. Charles E. Walton, of Cincinnati, president of the American Institute of Homœopathy, will make the principal address.

A Disgraceful Riot occurred at the Omaha Medical College, Thursday of last week, in which nearly one hundred students participated, and two of them were severely, perhaps mortally, injured. The fight took place between the dental and the medical students over the question of seats. At the beginning fists were the only weapons, but soon a railing was demolished and its severed parts were used as clubs, with serious results.

More Free Treatment by the New York Board of Health.—A few days ago notice was sent to physicians here by the health department that treatment for the prevention of rabies, according to the method of Pasteur, would be administered free to any person residing in Greater New York; that it would be administered on request to persons outside the city upon the payment of $50 for the virus used, and that to persons unable to pay that fee treatment might be administered without charge by direction of the board of health. The treatment will be carried out at the Willard Parker Hospital.

X-Ray Treatment of Alopecia.—A Viennese physician, Dr. Kienbock, claims to have caused hair to regrow on a bald head by treatment with Roentgen rays. The case reported was one of alopecia in a young man, cause not stated, but the doctor has not succeeded in remedying calvities senilis.

Presentation to Dr. Wheelock.—On the evening of November 14, 1900, the committee appointed for this purpose by the Alumni Association of the College of Physicians and Surgeons, medical department of Columbia University, presented to Dr. George G. Wheelock, of New York City, a testimonial in silver to commemorate the faithful and wise manner in which he had performed the duties of treasurer for the Association during the long period of twenty-four years. The testimonial bore the inscription: "Fidelitatis Causa."

Testimonial Banquet to Dr. Christian Fenger.—A testimonial banquet was tendered to Dr. Christian Fenger at the Auditorium Hotel, Chicago, November 3, 1900. Over five hundred physicians from all parts of the United States were present. The meeting was called to order by Dr. J. B. Murphy, who introduced as toastmaster Dr. Charles A. L. Reed, of Cincinnati. Letters and messages of regret from the officers of various State, county, and local medical societies in the East, West, North, and South were read. Dr. W. W. Keen, of Philadelphia, presented the loving-cup to Dr. Fenger. One side of the cup bore the inscription:

> "This great good man for noblest cause displays
> What many labors taught, and many days."

On the other side it read: "To Dr. Christian Fenger, on the sixtieth anniversary of his birth, from those who know and love him best—THE MEDICAL PROFESSION." Dr. Fenger accepted the loving-cup in a brief but felicitous speech.

The First New York State Conference of Charities and Correction was held in the Senate Chamber at the Capitol in Albany, on November 20, 21, and 22, 1900. This Conference, designed to meet annually in this State, has been inaugurated for the consideration of questions of practical importance with relation to the public and the private charitable and correctional work of the State, with the hope that the Conference will be able to exert a powerful force for good in securing intelligent action upon such questions. Conferences similar in purpose have for some time been organized and carried on in many of the States, principally in the West, and those who are well informed on the subject regard them as sources of beneficent influence. All who are officially connected with public or private charitable or correctional work in New York State, or who take an active interest therein, are invited to enroll themselves as mem-

bers of the Conference and to attend its sessions. There are no other tests of membership, and no membership fee is charged, the expenses of the Conference being met by voluntary contributions. The officers of the Conference were: *President*, Hon. William Pryor Letchworth, LL.D., of Portage; *Vice-Presidents*, Robert W. de Forest, of New York; Rev. Thomas A. Hendrick, LL.D., of Rochester: *Secretary*, Homer Folks, of New York; *Assistant Secretaries*, Frederic Almy, of Buffalo; Dr. John F. FitzGerald, of Rome; Clarence V. Lodge, of Rochester; *Treasurer*, Frank Tucker, of New York.

An Impostor.—Dr. W. Peyre Porcher, of Charleston, S. C., writes that a man impersonating himself, and claiming to have attended the meeting of the Congress of American Physicians and Surgeons in Washington in May last, has been victimizing many of the profession of that city by pretending to be in distress and borrowing money from them. The man is described as being between sixty and seventy years old, with a heavy gray mustache, about five feet eight or ten inches tall, and of rather spare build. There should be some way in which physicians could protect themselves from this class of scoundrels, and Dr. Porcher hopes that any one approached by this man will be on his guard and will be able to cause the swindler's apprehension.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending November 17, 1900. Medical Director C. H. White placed on the retired list of the navy from November 19th, having reached the age of sixty-two years. Passed Assistant Surgeon R. S. Blakeman detached from the *Pensacola* and ordered to Naval Hospital, Mare Island, for treatment. Assistant Surgeon C. S. Butler ordered to the *Independence*. Surgeon W. A. McClurg ordered to additional duty on the *Yankee*. November 14th.—Assistant Surgeon W. M. Carton detached from the *Indiana* and ordered home to wait orders. November 15th.—Passed Assistant Surgeon A. R. Alfred detached from the *Castine* and ordered to the *Culgoa*. Passed Assistant Surgeon M. K. Johnson detached from the *Celtic* and ordered to the *Brutus*. Assistant Surgeon H. C. Curl detached from the *Culgoa* and ordered to the *Castine*. Assistant Surgeon E. Davis detached from the Cavite naval station and ordered to the *Brutus*. Assistant Surgeon W. L. Bell detached from duty at Guam and ordered to the *Celtic*. Assistant Surgeon B. L. Wright detached from the naval hospital, Cavite, and ordered to the naval hospital, Yokohama, for treatment.

The Late Dr. Lewis A. Sayre.—In the death of Dr. Lewis Albert Sayre the New York Pathological Society loses the last of the members who brought it into existence. The first meeting of the society was held in Dr. Sayre's office on June 14, 1844, Drs. George A. Peters and Middleton Goldsmith participating in the formation of the new society. Dr. Sayre kept his interest in the society alive, occasionally attending its meetings, until the end of his professional activity. It is with a special sense of loss that the society sees fade from its list of active members this illustrious name, enrolled at its first meeting when "the oldest pathological society in the world," as he was fond of saying, was created.

The New York Pathological Society now records upon its minutes the death of Dr. Lewis Albert Sayre, and adopts the following resolution:

"*Resolved*, That the sympathy of the New York Pathological Society be extended to the family of Dr. Sayre in their bereavement, and that the above testimonial be published in the current medical periodicals. (Signed) W. P. Northrup, M.D., James Ewing, M.D., E. K. Dunham, M.D., *Committee*."

Obituary.

HORACE TRACY HANKS, M.D., LL.D.,

NEW YORK.

Dr. Hanks, whose death from Bright's disease occurred on Sunday last at his home in this city, was born June 27, 1837, in East Randolph, Vt. After completing his college studies he taught school in his native place for some years, and then began the study of medicine under a preceptor. His degree was obtained from the Albany Medical College in 1861. For two years after graduation he served in the Union army as acting assistant surgeon, and in 1863 entered upon the practice of his profession in Royalston, Mass. Here he remained but a short time and then removed to this city. Circumstances turned his attention almost from the first to gynæcological subjects, and he soon became recognized as an authority in that specialty. He was gynæcologist to the Demilt Dispensary from 1872 to 1882, and in 1885 was appointed professor of the diseases of women at the Post-Graduate Medical School. In 1875 he became assistant surgeon to the Woman's Hospital and was elected attending surgeon to the same institution in 1889. He was also consulting gynæcologist to the Tarrytown, Mt. Vernon, and St. Joseph's Hospitals, and to the Newark Hospital for Women and Children. He was a member of the New York Academy of Medicine, the New York Obstetrical Society, the New York State Medical Society, New York County Medical Society, the Medico-Historical Society, and the American Medical Association, and was a Fellow of the American and of the British Gynæcological societies. He was an honorary member of the Boston Gynæcological Society and the Dubuque Medical Society. He was a prolific writer for medical publications and invented a large number of surgical instruments for use in his specialty. A widow and two daughters survive him.

Obituary Notes.—Dr. Robert B. Brown died on November 15th at his home in Phillipsburg, N. J., at the age of seventy-six years. He was graduated from the medical department of the University of Pennsylvania in 1846. He served as surgeon in the Union army during the Civil War.

Dr. A. Miles died last week at his home near Dallas, Texas, at the age of ninety-four years. He was a native of Kentucky, but practised medicine in Texas for nearly sixty years. He served as surgeon in the Confederate army during the Civil War.

Dr. George W. Sparks died at Philadelphia on November 17th at the age of fifty-six years. He was graduated from Jefferson Medical College in 1865.

Dr. William T. Collins died at Camden, N. J., in November, at the age of seventy-one years. He was a graduate of Jefferson Medical College.

Progress of Medical Science.

New York Medical Journal, November 17, 1900.

An Operation Devised for the Treatment of Marked Prolapse of the Rectum in Women.—By J. Wesley Bovée. The patient was a woman aged thirty-five, who suffered from large external and internal hemorrhoids and a protruding roll of fully three inches of rectum that was thickened and much discolored. The uterus was of about normal size, with its cervix just behind the pubes and the fundus very low posteriorly. The hemorrhoids were first removed, then the abdomen was opened by the usual subumbilical median-line incision. The left ovary was of about three times its natural size and largely consisted of numerous cysts. The appendages were removed and the uterus was firmly fixed to the abdominal wall by four strong interrupted catgut sutures, which passed through a considerable portion of the uterine fundus at the top and the principal fascia of the abdominal wall on either side of the incision. The rectum was now drawn upward until it was fairly tense, and was so held by an assistant until it was sutured to the cul-de-sac and posterior wall of the uterus, up to the abdominal wall. This was done by a running catgut suture. It completely divided the retro-uterine pelvic cavity into two equilateral ones. The patient was doing well eight months after operation, with no relapse.

Delirium Tremens.—C. J. Douglass thus states his views as to the correct method of treating this condition. First, patients should be put to sleep with apomorphine, which can be done in a few minutes without danger and without emesis. Secondly, they should not be restrained by physical force, as this adds to their suffering and prolongs and increases delirium. Thirdly, they should be allowed alcohol in some form. Fourthly, the patients should be nourished with milk, egg-nog, or some other liquid food. Delirium tremens seldom affects those who have not been deprived of proper nourishment for some time. Hence easily assimilable food is indicated.

Pernicious Anæmia; Report of a Case.—G. R. Trowbridge states that the etiology of this affection is very obscure, there being no known or appreciable cause. As yet it is impossible to say whether the disease is produced by a defective hæmogenesis or hæmolytic process. The points on which to base a diagnosis are as follows, and in every suspected case include an examination of the blood: (1) Greenish-yellow tint of the skin. (2) Dyspnœa and rapid pulse without pulmonary symptoms and a proportionate rise of temperature. (3) The intense oligocythæmia. (4) The presence of macrocytes and microcytes. (5) The steady and uninterrupted progress of the disease toward a fatal termination, and the inefficiency of treatment. The prognosis is always unfavorable. Arsenic is the only drug which seems to have a beneficial effect in these cases, and then it is only slight and not permanent and only temporarily checks the progress of the disease. The writer concludes by saying: In cases of apparent chlorosis and primary anæmia in which there is present the greenish tint of the skin, together with dyspnœa, palpitation, and general malaise, one should not depend on symptoms for the diagnosis, but should let the blood examination decide whether one is dealing with either of these diseases or with a case of pernicious anæmia.

The Surgical Importance of Jaundice.—Archibald Maclaren concludes: (1) That slight attacks of jaundice are of comparatively little surgical importance, and that the majority of cases of surgical disease of the biliary passages have no jaundice at all. (2) That persistent jaundice, especially if progressive, is usually a contraindication; (3) while on the other hand intermittent, deep jaundice, especially if associated with chills and a rise in temperature, denotes a stone in the common duct which urgently demands removal. The writer also states that about half the patients who during life present symptoms of carcinoma of the liver are jaundiced. The surgery of cancer of the liver is very unsatisfactory. The disease is, in his experience, very aggravated, and the end is even hastened by an exploratory operation. Cholecystotomy and drainage give relief except in cancer of the common duct. Cancer of the gall bladder, which is almost always found in cases when gall stones have existed for years, should be removed if the liver be not too extensively infiltrated.

Boston Medical and Surgical Journal, Nov., 5, 1900.

Feeding in Typhoid Fever, with a Report of Cases.—George W. Moorehouse urges the use of a more generous diet in the treatment of typhoid fever than is the usual practice, and describes milk diet, liquid, soft typhoid, typhoid convalescent, and full typhoid diets. Out of one hundred and fifty cases put on soft diet there were thirteen deaths, or a mortality of 8.67 per cent. Dr. Bushuyev, a Russian surgeon, reports the result of experiments upon one hundred and fifty-four patients in a hospital. Seventy-four, treated by a colleague, received two litres of milk and one or two soft-boiled eggs in the day. Bushuyev's eighty patients were put upon a liberal diet. The general mortality was ten per cent. on the liberal and 12.1 per cent. on the milk diet. The average duration of the fever after entrance was 18.9 days for those liberally fed, and 22.3 days for those on milk. The average stay in the hospital was forty-two days for those liberally fed, and 49.2 days for the others. Of the patients liberally fed only 8.3 per cent. were discharged incapable of duty, but of those who were kept on a milk diet 15.4 per cent were so discharged.

Three Cases of Gunshot Wounds.—A. Farenholt reports three cases. In the first a youth was shot in the head by a Spanish Mauser ball, calibre 8 mm. The wound showed that a modern high-power bullet, passing through a bony cavity at a very short range (two feet), may not cause a "ragged and enlarged opening" at the wound of exit, as we are so often reminded it does at greater ranges. In the second case a 45-calibre Remington ball gave a round and clear-cut wound of entrance and a gouged-out, large and ragged wound of exit. In the third case, a Mauser ball, at a distance of seventy yards, gave a rather ragged wound of exit.

Iodine Used Hypodermically in the Treatment of Pulmonary Tuberculosis.—Alfred Careno Croftan declares that iodine is peculiarly a drug against which different subjects show marked idiosyncrasies. The chief symptoms observed are emaciation, usually accompanied by profuse sweats, some pyrexia, and an accelerated pulse; a peculiar psychical depression develops a form of hypochondriasis ("anxietas"). In the light of our theoretical beliefs the administration of iodine should act curatively in pulmonary tuberculosis. Accurate dosage is essential to the success of the plan of treatment that is being advocated; too large doses will certainly aggravate, too small doses will be inefficient. Iodipin injections were tried only on carefully selected cases. Twenty-seven cases have so far been treated with good results; nineteen were cases of incipient tuberculosis with only circumscribed areas of infection in one or the other of both apices. The results obtained so far are not conclusive, they are only suggestive, although they now appear to be sufficiently striking to warrant an optimistic view. The sooner the disease is recognized and treatment begun, the better the prognosis. Iodipin was employed in the form of the ten-per-cent. preparation, and the injections were made into the subcutaneous tissues between the skin and the muscle, preferably in the gluteal and interscapular regions. Beginning with one drop of iodipin, which, to give the necessary bulk for hypodermic administration, was dissolved in half a drachm or so of sterilized oil, the injections were gradually increased, one drop being added to the dose each day. The dosage was regulated by the symptoms: as soon as an improvement became apparent, the dose exhibited at the time was continued for a period of thirty to sixty days. If the quantity at first acting beneficially seemed to grow insufficient, the dose was again increased drop by drop; more than sixty minims a day have so far never been given. The writer believes pulmonary tuberculosis in its incipiency, before it has become a mixed infection, to be one of the most easily curable of bacterial diseases.

Symptoms and Diagnosis of Hypertrophy of the Pharyngeal Tonsil.—George Morgenthau states that the most common of these symptoms is the excessive discharge which flows either into the nasopharynx or into the nose. Finally, chronic rhinitis results. The children become mouth

breathers. Infants are sometimes unable to nurse at the breast. Nosebleed sets in often. The nasal discharge is apt to excite eczema at the introitus, thickening and roughness of the upper lip, etc. Impairment of smell and taste often succeed chronic inflammation of the nose. Laryngeal and bronchial symptoms intervene: cough, hoarseness and false croup, and bronchitis and bronchopneumonia. Adenoid growths are often accompanied by nervous disorders. Major ascribes enuresis nocturna to carbonic-acid-gas poisoning from insufficient ventilation of the blood, the breathing being too superficial because of the stenosis; of this, interrupted sleep and snoring are a further result. Various authors explain differently the chest deformities. In extreme cases the anatomical deformities of the buccal cavity are marked. The patient may appear stupid but is not necessarily so. Adenoid growths are the most prolific cause of certain diseases of the ear in childhood, excepting, perhaps, the infectious diseases. As to the diagnosis, the characteristic appearance, the manifold signs of nasal stenosis, and the sound of the voice (which, to be sure, is very similar in paralysis of the soft palate), combined with the aural symptoms, make the diagnosis possible almost at a glance. Rhinoscopy offers an efficient aid.

Massage of the Eyeball.—Casey A. Wood believes that in the main indirect massage with the pulp of the finger placed on the skin of the lids is to be preferred. Direct massage, especially of the conjunctiva, is valuable and sometimes preferable to the indirect method, but the latter is usually sufficiently efficacious, is less difficult, and is more readily borne by most American patients. Indirect massage should never produce actual pain. If the lids are to be treated the patient should look down when the upper lid is being massaged, and up in the case of the lower lid. If the cornea is to receive attention the patient should look straight forward. Once daily to twice a week constitutes the range of frequency of these applications. The writer then speaks of several remedies used. In massage for its own sake cod-liver or pure castor oil is used. He believes in mercurials of various strengths, combined with all sorts of oleaginous excipients. He greatly favors the old citrine ointment. The patient, half an hour after lid friction, should not experience any added discomfort. The writer believes that massage in young subjects especially lessens the opacity following ulcer of the cornea. If applied early, it promotes the removal of the surrounding infiltrate that would otherwise remain. In the same way it is valuable in the treatment of interstitial keratitis.

Use and Abuse of Potassium Iodide in Ophthalmic Practice.—The following conclusions are presented by Albert Rufus Baker: (1) Iodide of potassium should generally be administered in rapidly increasing doses until from gr. i.-d. is given daily. (2) The drug should always be given after eating, and well diluted with water. (3) Frequent hot baths are essential to the best results in the use of the remedy. (4) Not infrequently large doses will be tolerated when smaller ones cannot be well taken. (5) The use of the large dose is not limited to syphilitic cases. (6) Large doses are indicated in optic neuritis, ocular paralysis, choroiditis, serous iritis, and in relapsing iritis, cyclitis, and interstitial keratitis. (7) It is contraindicated in gray atrophy of the optic nerve and in most cases of postneuritic atrophy. (8) Albumin in the urine, generally speaking, is a contraindication for large doses of iodide. (9) Young children do not take the iodide kindly, and it should be administered cautiously. (10) The remedy is of doubtful value in early syphilitic iritis. (11) Large doses are of doubtful utility in the removal of post-operative exudates, but should be given further trial.

Diabetes Mellitus in Children.—Leopold F. W. Haas concludes that: (1) Diabetes occurs more frequently in children than is generally supposed. (2) Uranalysis is just as important an element in the scientific diagnosis of disease in children as it is in adults. It is to be regretted that the general practitioner rarely realizes this fact. (3) There is a possible etiological connection between peliosis rheumatica and diabetes. The pathogenesis of both conditions is so obscure, however, that speculation on this question can only point out a direction for further research.

The Etiology of Yellow Fever.—Eugene Wasdin quotes Sternberg in a recent note: "From Wasdin's point of view the question of yellow-fever etiology is settled." The author adds that nothing is more certain than that fact, and then appends his reasons for the statement. Laborious clinical observation has culminated in the formulation of a group of infectious diseases, called the "acute infectious diseases." They have characteristics in common; primarily, they are infectious; they are characterized by clinical symptoms due to the influence of intoxicants; they are all specific infections; many of them are caused by vegetable micro-organisms of low type. Clinically, these diseases closely resemble each other until the development of their specific symptoms, after which they are readily diagnosticated. Pathologically the chief disasters arise from the influence exercised by the toxins formed by the organisms. In some of these diseases the infecting organisms also pass into the circulation and add their effect to that of the toxins. Co-instantaneously there are developed two inherent forces, or qualities, in the infecting germ—toxicity and septicity. The germs, intensely toxic, produce a reaction resulting in the fatty degenerations and at times the necroses in the parenchyma of the organs. Those intensely septic are characterized by more prolonged clinical symptoms, less marked fatty changes, and more marked necroses in the tissues. Each infecting organism is specific, and it is only so when it has entered into contact with the living tissues; when, if the environment is propitious, this potential becomes a developed force. When these developments are mixed the pathological changes are found to be combined. When the toxic potential is strongly developed there will arise the acutely toxic cases; if it is only slightly developed, such cases will be ephemeral; if the septic potential is developed, either alone or in conjunction with the toxic, there must arise the septic cases of these diseases. The three types of cases named are and have been recognized thus far only in yellow fever (Sternberg), although they may all now be recognized in the other acute infections. The writer continues that it is in the application of this law to the acute infection of yellow fever, explaining its symptomatology and its pathology upon these firm facts, that he now contends that yellow fever cannot be rudely torn from its place in the list of acute infections and placed, as Reed and Carroll would have it, among the accidental, artificial inoculations, which appears to be the fate of the malarial fevers at this time. Each one of the specific infectious organisms may be able, under artificial inoculation, to produce its specific disease, but this does not remove these diseases from the list of the natural infections.

Carcinoma of the Rectum.—John B. Deaver regrets that more radical surgery than that advised is not permissible; by which he means the removal of the lymphatic glands of the mesosigmoid, in this wise absolutely cutting off the lymphatic circulation between the site of the disease and the general lymphatic circulation. If this was possible, the outcome of these operations would be more promising. But as this is not possible, early and radical operation is all the more urgently called for. When the growth occupies the rectum high up, the writer opens the abdomen in the left iliac region. If it is then determined that the growth with the rectum can be taken out through a posterior incision, the sigmoid is divided transversely and removed with its mesentery as far down as the growth, when the lower opening is closed and the margins of upper opening are stitched to the margins of the upper part of the incision, closing the lower part of the incision entirely.

On the Influence of Fatigue on the Minute Structure of the Kidney and Liver.—By Guido Guerrini. In the kidney the grosser modifications of structure are in the cells of the convoluted tubules and of the ascending part of the loop of Henle. The corpuscles of Malpighi and the collecting tubes are nearly always normal. In the affected cells the modifications of structure are, naturally, in relation with the degree of fatigue undergone by the animal. The more fatigued a dog is the more profoundly altered are the cells. In animals already much fatigued the following appearances may be observed. The protoplasma loses its

unsual aspect and becomes homogeneous and granular. It appears that the cellular body enlarges, sometimes little, sometimes so much that in a transverse section all the openings of the canals seem to be closed by the swollen cells. The edge between the cells becomes uncertain and sometimes disappears altogether. In animals still more fatigued the minute modifications of the cells of the convoluted tubules are much greater. It is seen, in fact, that the borders of the cells which surround the opening of the canals fray out and break, and that the cellular protoplasm shows here and there rarefied points, vacuoles and cracks, and finally crumbles away into a fine detritus which collects in the opening of the tubules. In the midst of this detritus normal nuclei are sometimes found, sometimes lumps or granular masses which stain like the nuclei. This degenerative process almost always attacks a certain number of cells, but sometimes it is seen only in a group of a few diseased cells which are in the midst of several normal ones.

The minute modifications of structure of the liver cells are much less than are those of the kidney cells, and they appear conspicuously only in the liver of those dogs in which the modifications of structure are the greatest. They are as follows: From the beginning all the cellular protoplasm appears homogeneous, cloudy, and granular. The cellular body enlarges and the edge between the cells becomes uncertain and sometimes disappears altogether. Sometimes the little biliary canals are evidently compressed, whereupon the protoplasma of the liver cells appears rarefied, full of knots, spongy, and very dark from biliary pigment.

The Physiology and Pathology of Inheritance, or What do We Inherit from Our Parents?—Thomas Oliver says that from a physiological point of view there is considerable evidence to show that mental, not less than physical, qualities are transmitted; that pathologically such a disease as haemophilia is inherited, and that when there is a family history of phthisis and cancer there is, especially as regards phthisis, a greater liability to the disease than when a family shows no such record. He believes that the influence of inheritance, however, has been exaggerated. Tuberculous disease is inherited, but only in the same sense as are other diseases that are due to microbes: it is in the form of an enfeebled resistance on the part of the tissues. Pulmonary phthisis seems to exhibit a kind of inheritance that is particularly its own, but on scrutiny this is found to be largely due to the domestic character of the malady which is encouraged by our home life, insanitary dwellings, overcrowding of the poorer working-classes, infection, Britain's changeable climate, dusty occupations, and ill-assorted marriages.

Two Cases of Hemorrhagic Pancreatitis.—J. H. Bryant reports the cases of two men, aged thirty-six and twenty-two respectively. The first case was diagnosed as one of perforating gastric ulcer, and the abdomen was opened, with the finding of the condition named in the title. Death ensued on the fourth day. The autopsy showed (and this is the remarkable feature of the case) fat necrosis outside the peritoneal cavity. There was fat necrosis of both the mediastinal and pericardial fat, and the cavity of the abdomen was at the time of operation distended with bile-stained, serous, sterile fluid. This latter condition was especially noticeable in the second case in which the same diagnosis was made before operation as in Case I. No fat necrosis was found. The tissues in the neighborhood of the bile passages and the pancreas had a swollen and sodden appearance and were all very deeply stained with bile. It was thought that bile might have escaped into the abdominal cavity by either the blood-vessels or lymphatics, or both.

An Interesting Case of Amenorrhœa.—W. J. H. Hepworth reports the case of a young married woman aged twenty-three years, who had had two children and suspected a third pregnancy, as she had menstruated only once since her infant was born, and that was six weeks after birth. The patient found as soon as she left London and went to the country that her sickness would return at the regular times, but would not if she remained in town. By leaving town for two days each month it was possible for her to regulate the monthly function without difficulty.

Clinical Lecture on Progressive Pernicious Anæmia with Spinal Symptoms.—Sir Dyce Duckworth cites the case of a man aged thirty-six years, afflicted with this disease. As the result of treatment by rest, good diet, with wine, red bone marrow, and the action of arsenic, the patient improved, although he never recovered his original health, having been a vigorous and robust-looking man. Later he had a relapse, and in addition he gave evidence of the onset of some grave disorder of the spinal cord. At this time the red cells numbered 1,600,000; white cells, 5,000; hæmoglobin, twenty-seven per cent.; the patient sweated profusely, and was very exhausted and languid. About two weeks later there was weakness in all muscles of both legs, no definite paresis. There were complete loss of sense of position, and nearly complete anæsthesia below the level of the patella, but dipping down the popliteal space in a loop over the calf, in the "small sciatic area." Four days later loss of rectal control occurred. About five weeks from the time the above blood count was taken, the red cells had dropped to 1,500,000; hæmoglobin, thirty-two per cent. Five days later he died; at 6 A.M. the temperature rose suddenly to 104 F. The respirations were 34 and the pulse 120, at times very small. About an hour before death the temperature rose to 105°. The pulse was 136, and of very small volume. One hour after death the temperature was 106.2°. The present conception of this distressing malady regards it as the result of a special form of blood destruction, so-called hæmolysis, occurring in the course of the portal circulation, induced by the action of some toxic matter produced in and absorbed from the alimentary tract. The disease is therefore a chronic infective form of toxæmia, which induces profound anæmia, and it is surmised that this toxin is of bacterial origin.

The Treatment of Dysentery.—Wilfred Watkins-Pitchford gives his experience in the treatment of this disease in Natal during the first part of this year. As the patients brought to the hospital were nearly all beyond the first stages the saline aperients met with little success. ipecacuanha also was disappointing, probably for the same reason. The tincture of "monsonia ovata" appeared to produce no effects whatever except nausea and depression. Greater success attended the use of mercury perchloride in mixture with bismuth and opium, and several of the patients who recovered undoubtedly owed much to this combination. "Izal" in 5-minim doses certainly produced amelioration of symptoms. Izal combined with bismuth and chlorodyne gives a most satisfactory result. The formula used by the writer is: ℞ "Izal," ♏ iii.; bismuthi subnitratis, gr. x.; tincturæ chloroformi et morphinæ, ♏ viii.; mucilaginis acaciæ ad ℥ i. To be taken every two, four, or eight hours, according to the severity of the symptoms. Milk is not a suitable diet for this disease. Beef-tea and bread with butter satisfy, and leave a residue which appears to cause but little colic or rectal irritation. Great risk must frequently accompany the giving of rectal injections, especially when combined with abdominal massage. The coexistence of enteric fever and dysentery or their occurrence within a short interval of one another is not uncommon.

Enteric Fever in South Africa; Effective Sterilization of Excreta.—H. A. Cummins, in the epidemic of enteric fever at Bloemfontein, obtained from the sanitary contractor a large thirty-gallon iron "jackpot" into which were poured about two gallons of 1:20 carbolic solution and subsequently the excreta. The pot was kept boiling day and night. According to requirements the contents of the pot were emptied, but always a sufficient, heated residue was left to affect the next stool emptied. Carbolic solution was poured in if necessary to make up for loss by evaporation. The contents were thus kept fluid, and no charring could occur. In this manner the practically instantaneous sterilization of each stool the moment it left the bedpan was secured day or night. There was practically no smell from the fumes. As a result of bacteriological experiment, five nutrient agar tubes which were inoculated from the pot developed no sign of bacterial growth, while one tube inoculated from the contents of a bedpan about to be emptied into the cauldron showed about one hundred well-marked colonies.

Notes of a Series of Cases of Glandular Fever Occurring in Epidemic Form.—Leslie Durno makes this report. With the exception of one adult, the ages of the patients ranged from two and a half to thirteen years. In every household in which the malady appeared very few of the younger members escaped. The illness commenced with headache, nausea and sickness, pain in one side of the neck, and, in by far the greater proportion, of the left side. The temperature ranged from 100 to 105° F. The pulse rate was high. Constipation was the rule. The lymph glands on the affected side of the neck became swollen and tender. Acute anæmia developed rapidly and in some cases was extreme. There were no deaths. The disease is highly infectious. Sodium salicylate with one or two calomel purges in the feverish stage, arsenic and iron during convalescence, appeared to give good results. An important element in treatment is

to maintain as thorough an antiseptic state of the mucous membrane of the throat and pharynx as possible.

The "Hepatic Odor" in Abscess of the Liver.—W. K. Hatch calls attention to the peculiar odor present in patients suffering from abscess of the liver. In one patient who had been treated for chronic diarrhœa of two months' standing, the presence of this smell guided the writer to suspect the liver, although as the temperature was subnormal and the liver only slightly enlarged the medical attendant had not considered the liver at all affected.

Apomorphine as a Hypnotic.—E. W. Adams administered a hypodermic injection containing gr. $\frac{1}{15}$ of this drug to an alcoholic patient. The expected did not occur. In about twenty minutes she was quietly sleeping. Instead of aiding the ineffectual retching that was present, this latter was quelled by the exhibition of the drug.

Treatment of Inflammations of the Uterine Adnexa by Water at 60 C.—A. Suarez de Mendoza reports his success with this treatment. In the last two years he has treated two hundred and forty-two women by vaginal injections of water at 60°. Some of these patients, one hundred and five in number, were afflicted by more or less serious lesions of gonorrhœal origin. In fifty-two cases the infection was traced to the puerperium. In the great majority of cases, and whatever the origin of the infection, at the fifteenth or twentieth injection, sometimes even before, improvement begins and makes rapid progress. In those cases which are not extremely severe, cure appears perfectly established. The technique is very simple. There is a special cannula in order to avoid the transmission of heat to the skin, which is never touched by the water; and as the vaginal mucosa is not very sensitive to heat, the temperature above indicated is comfortably borne. The time taken for the injection is ten minutes. The patient assumes the obstetrical position, and the reservoir of hot water is placed at a height of 60 cm. above her; the cannula lubricated with vaseline is introduced into the posterior cul-de-sac, and the stop-cock opened. Generally at the end of five or six seconds the water flows out in a regular stream, but sometimes the opening of the cannula is obstructed by a fold of mucous membrane, which necessitates a few movements of the instrument in order to start the flow. The cannula must be carefully supported in order that none of the water escape over the patient's exterior, for the sensation of burning would prevent the proper application of the injection. Consequently, in case the fourchette is torn, its borders must be gently pressed together to prevent the water from escaping between the cannula and the inferior vaginal wall.—*Annales de Gynécologie et d'Obstetrique*, Septembre et Octobre, 1900.

Hygiene and Therapeutics of Puberty and of its Diseases in Woman.—Paul Dalché believes that as far as possible the young girl at the period of puberty should live at home, in order to avoid privation and fatigue. The child cannot have the freedom of air and sun in even the best regulated school that she is free to enjoy at home. The diet should be generous; the meals should be frequent and be composed to a great extent of roasted or broiled meats and wine. Constipation should be avoided. Cold should be avoided at the menstrual epoch, especially in the young. Clothing should be carefully chosen; it should not compress the organs; it should protect efficiently against variations of air and climate. Exercises, gymnastic and other forms, as well as hydrotherapeutic measures should be intelligently prescribed. Faulty attitudes, so often assumed, should be condemned; if indulged in, they should be corrected. The eyes should be carefully watched. The author quotes from Lawson Tait, who believes in the association of the two sexes. He states that although it may be a pure coincidence, yet he has noticed ovarian hyperæmia especially in young girls who have no brothers or whose brothers are younger than they. Leucorrhœa is the most frequent and the earliest affection of puberty. It results from the hyperæmic state which accompanies evolution of the uterus, and which provokes a hypersecretion of the mucosa, but it is also often an expression of a debilitated condition. This discharge may cause a vulvar eruption. For such a case boiled hot water should be used, the surfaces isolated, and talcum powder applied. The writer lastly considers vulvar pruritus and eruptions with their treatment.—*Bulletin General de Thérapeutique*, October 23, 1900.

Researches in the Etiology of Cancer and the Pathogenic Blastomycetes.—Léopold speaks of the results of his investigations of this subject as follows: There can be seen in the fresh tissue of almost every malignant neoplasm brilliant bodies, partly round, partly biscuit-shaped, in which can be shown reproduction and segmentation. These bodies, which were not confused with cocci or degenerated cells, could be considered only as blastomycetes by the fact that they were not changed in a solution of caustic soda or potassa, or in hydrochloric or nitric acid. After many trials pure cultures of blastomycetes were obtained from four malignant human neoplasms. These were obtained from a cancer of the ovary, from a cancer of the breast and the axillary glands, and from cancer of the uterus. The blastomycetes were therefore obtained from a fresh cancer of the ovary. The pure culture can be obtained from fresh carcinomatous tissue. The injection of this pure culture in the testicles of a rat was followed by the development of a large number of nodules in the peritoneum to which the animal succumbed. Blastomycetes taken from these nodules give pure cultures. Consequently, there is no doubt that blastomycetes can be the cause of malignant neoplasms in man, and that inoculated into an animal they cause a neoplasm in it, which destroys life.—*Annales de Gynécologie et d'Obstétrique*, September and October, 1900.

Cervical Metritis.—Pozzi presents the following conclusions on this subject: (1) Acute or chronic inflammation of the cervix can exist for a long time without invading the body of the uterus. (2) Nevertheless, the acute lesions of the cervical mucosa easily extend to the mucosa of the body, and the chronic lesions of the cervical parenchyma of inflammatory origin (sclerous and sclerotic degeneration, partial or total) promptly react on the nutrition and anatomical condition of the entire uterine body. (3) The operation of trachelorrhaphy is inferior to the biconical resection of the cervix, more or less modified according to circumstances. It ought to be abandoned. (4) There are a large number of acute, subacute, or chronic inflammations of the cervical mucosa in nulliparæ, which are dependent on the narrowness of the external orifice and on the insufficient drainage resulting therefrom. The most important part of the treatment is then to reconstruct by operation in a durable manner an orifice large enough for the cervix.—*Annales de Gynecologie et d'Obstetrique*, Septembre et Octobre, 1900.

Semeiology and Treatment of Refusal of Food.—After reviewing the causes of this disorder, which may be either physical or psychological (gastro-intestinal disorders being among the first; melancholia, a maniacal state, general paralysis, degeneracy, acute and chronic alcoholism, neuroses, epilepsy, and hysteria being psychological causes), Paul Garnier and Paul Cololian discuss the treatment of the condition. Before resorting to artificial alimentation, the reason for the refusal of food must be ascertained and the cause removed if possible. Moral suasion is often very efficacious. Sometimes if victuals are placed within reach and the patient believes himself unobserved, he will eat. The various methods of artificial feeding are described, after which the kinds of food suitable are enumerated. This should be liquid: milk, chocolate, eggs, scraped meat, purée of vegetables, and a little peptone. Salt must not be omitted. Food should be given once or twice a day. Cod-liver oil is excellent for this condition.—*Gazette des Hôpitaux*, October 23, 1900.

The Accidents of Internal Arsenical Medication.—After taking up in detail the troubles not infrequently attending the administration of arsenic, according to Dupoux, the writer speaks of the treatment both preventive and curative: The physician should be assured of the good condition of the eliminative organs and of the digestive apparatus before prescribing arsenic. The drug should be given in the best form and under the best conditions. It should not be given to the young. The dose should be increased little by little, stopped at the end of fifteen days, then begun again. At the least sign of intoxication the doses must be diminished, and wholly stopped in case of

severe symptoms. All the means tending to favor elimination of the poison should be used—milk, baths, friction, purgatives, diuretics, etc. Alkaline remedies might be prescribed together with arsenic, such as bicarbonate of sodium, which would assist in eliminating the poison and favor digestion.—*Gazette des Hôpitaux*, October 25, 1900.

Nasal Cough in Tuberculosis.—L. Revillet sums up the diagnostic points as follows: An irregular cough occurring especially at night in the dorsal decubitus; disproportion between the cough and expectoration; diseased nose—polyps, vegetations, hypertrophy or atrophy of the mucosa, ozæna; the posterior pharyngeal walls bathed in mucopurulent discharge. The treatment consists in washing the nose with boiled salt water, or with the addition of a little boric acid or lemon juice. Or a mixture may be used, made of boric acid, menthol, and chlorhydrate of cocaine. A nasal douche of sulphur water gives excellent results. If the secretions persist, cauterizations of the mucosa with the galvano-cautery may be employed.—*Lyon Médical*, October 28, 1900.

Deutsche medicinische Woch., Oct. 25 and Nov. 1, 1900.

Functional Diseases of the Heart.—H. Hoehhaus believes that at least one-third to one-half of all neurasthenics suffer from cardiac neuroses, and that a somewhat smaller percentage of hysterical patients are similarly afflicted. Any of the conditions predisposing to these two affections may also cause functional disease of the heart, though additional factors, such as intoxication with tea, coffee, nicotine, or even alcohol, bodily or mental overexertion, or sexual excesses are nearly always present. Usually the lesion is due to the summation of several minor causes of this nature, while reflex disturbances of the gastro-intestinal tract or the genital apparatus may also play an important rôle in the etiology. The symptoms may be grouped under (1) the subjective sensations of the patient, which may run the gamut from slight feelings of pressure in the cardiac region to the severest spasms of angina-like pain, and (2) the objective alterations in the heart's action. In most cases this is rapid and forcible, more rarely it is depressed, while arrhythmia is not as uncommon as usually supposed. In many instances the diagnosis is apparent at once, but often even after long observation and consideration of the history the differentiation between organic disease, especially a beginning muscular insufficiency and pure neurosis, is of the greatest difficulty. The author has found careful determination of the blood pressure by the instruments of Gärtner or Riva-Rocci and Roentgen-ray illumination to be the most helpful aids. Whenever the arterial pressure is found markedly to exceed a value of from 130 to 140 mm. of mercury, the assumption is warranted that the disease is purely functional, while the fluoroscopic observation of the neurotic heart shows that its contraction is not only unusually jerky and sharp, but that the difference in size between the systolic and diastolic phases is abnormally great.

Observations on Copper Workers.—L. Lewin has attempted to settle the mooted point as to the toxic action of copper taken into the body in small amounts for long periods of time and answers the question by denying the possibility of any chronic copper poisoning analogous to that produced by lead. Previous animal experimentation has furnished evidence giving color to such a view, but decisive evidence can be obtained only by observations on those engaged in handling the material industrially, and therefore exposed to receive small amounts daily for years at a time. The result of such observations conducted by the author leads him to conclude that while as an immediate consequence the inhalation or swallowing of considerable quantities of metal may lead to local disturbances of the mucous membranes primarily concerned, these effects are but slight and readily pass off without sequelæ, and furthermore that in man there is no such thing as chronic copper poisoning. When symptoms exist among those exposed to daily contact with the metal they are to be ascribed to other grounds than this, and the fear that minute amounts of organic or inorganic salts of copper, such as might exist as intentional or accidental contaminations of food products, are dangerous to health is wholly groundless.

The Gonorrhœal Nervous Diseases.—A. Eulenburg calls attention to the fact that while nearly every other part of the body has its distinct series of maladies to which a gonorrhœal etiology is attached, the nervous system appears to have been somewhat neglected in this regard. This omission he then proceeds to rectify by describing fourteen cases of nervous disease apparently directly traceable to a specific urethral infection. In considering the secondary nerve lesions due to the gonococcus three classes are to be made: (1) Neuralgic affections, especially gonorrhœal sciatica. (2) Various forms of muscular atrophy or dystrophy, and atrophic palsies. (3) Gonorrhœal neuritis in its more restricted sense, as mononeuritis or polyneuritis, and gonorrhœal myelitis. In order to establish a connection between the infection and the disease a single coincidence of symptoms is not sufficient, but a general consideration of the points involved in each particular case is necessary. Important factors are the simultaneous occurrence of urethritis with or without the presence of gonococci in the secretion, the existence of other metastatic specific lesions, epididymitis, endometritis, endocarditis, or arthritis; or symptomatic peculiarities of the nerve affection itself.

Do Any Genetic Relationships Exist between Appendicitis and General Neuroses?—Ossian Schauman answers this question in the affirmative, and as evidence cites the occurrence of appendicular inflammations in several members of each of fourteen different families, in twelve of which there was a hereditary neurotic taint. Furthermore, in investigating seventy-five cases in which the disease had befallen but a single member of the household, it was found that in the majority of instances either the patient or a near relative gave evidence of nervous degeneracy. In order to establish a connecting link between the neurotic condition and the intestinal lesion the author adverts to the well-known fact that neurasthenia and various forms of enteroptosis are frequently found in the same individual, and suggests that the abnormalities of position may either provide more favorable conditions for the development of the bacterial virus which represents the immediate cause of the disease or may lessen the resisting-power of the appendix.

The Determination of the Functional Integrity of the Kidneys before Operation by Means of the Freezing-Points of the Blood and Urine.—Hermann Kümmell gives these four points as being the most useful in indicating whether the state of "the other kidney" is such as to permit extirpation of the diseased organ. (1) Estimation of the urea. (2) Determination of the freezing-point of the blood. (3) Determination of the freezing-point of the urine, if possible obtained from the two kidneys separately by ureteral catheterization. (4) Examination of the separated urine from the two kidneys, with and without the previous administration of phloridzin or methylene blue. The value of the blood investigation, which gives far more reliable results than the urea determination, rests on these facts. The degree of concentration of any solution is directly proportional to the distance its freezing-point lies below that of distilled water, and the normal freezing-point of human blood has been found to lie between -0.55° and -0.57 C. If the kidney function is impaired an increase in the amount of solids takes place, with a corresponding lowering of the freezing-point. If one kidney has been thrown out of function, but the other is capable of carrying on the work unaided, *i.e.*, when a nephrectomy would be permissible, the freezing-point will invariably be found to be normal, and *per contra* if this is lower than the limit given, operation is contraindicated. The urine examination is conducted on similar principles but is less reliable in practice, owing to the physiological variations being much greater.

Processes of Compensation.—Adolf Bickel says that a loss of function of one part of the nervous system may be vicariously compensated for through the adaptability of other portions of the mechanism. This mutual interchange of function is more prominent the higher we go in the scale of animal development. Thus in the lower animals (frogs) the disturbances primarily attending injury to the central nervous system persist unchanged indefinitely, while in more highly developed organisms (dog) such evidences of impaired function may in the course of time be entirely obliterated through the re-education of other centres. This physiological fact is of importance, since it affords a scientific basis for the systems of compensatory training advocated in various nervous diseases, especially locomotor ataxia, by v. Leyden, Frankel, Goldscheider, Jacob, and others.

The Substitution of Eucaine B for Cocaine in Bier's Method of Medullary Narcosis. F. Engelmann adds another note to the universal cry of warning which is beginning to make itself heard from all quarters against the premature enthusiasm of the advocates of this method. In an attempt to find a less dangerous substitute for cocaine he employed eucaine, which has the same anæsthetic power coupled with only one-third of its toxicity. One-sixth of a gram of the drug was injected into the author's medul-

lary canal, but no anæsthesia resulted, and exceedingly distressing headache, backache, vomiting, dyspnœa, palpitation, etc., supervened, the effects not passing off entirely until nine to ten days had elapsed. The much-desired, harmless but effective spinal anæsthetic is therefore apparently not to be looked for in eucaine B.

Hemorrhagic Erosions of the Gastric Mucosa.—Carl Parises gives a general summary of the views on this condition of the gastric mucosa. The principal symptoms are a burning pain over the entire gastric region, a lessened ingestion of food, and a marked emaciation. Nausea is often present, but actual vomiting is rare. Pain comes on from fifteen to forty-five minutes after taking food, and is distinctly burning in character and not, as in ulcer, crampy and nagging. Moreover, it is not localized, as in the latter condition, but is diffused. Examination by means of the test-meal, etc., shows scarcely any departure from the normal as regards motor functions, bits of mucosa in the washings, and in the majority of cases a subacidity. The affection is due to circulatory disturbances in the mucosa, leading to its acute inflammation, and spasm of the muscularis. Authorities differ as to the specificity of the lesion, some claiming it to be a distinct affection, while others maintain that it is merely a feature of chronic gastritis. Treatment should consist of irrigation with a 1:1,000 to 1:2,000 solution of silver nitrate, which is allowed to remain in the stomach for a few minutes and is then withdrawn, being followed by irrigation with decinormal salt solution. Diet is in a general way as for ulcer. Many patients are able, however, to take a more liberal diet than are ulcer patients.

The Fracture of the Greater Tuberosity of the Humerus.—By H. Wohlgemuth. This condition is of rare occurrence, but is observed in certain cases of dislocation and fracture of the neck of the bone. Two cases are reported by the author, who finds in this by-accident the explanation of loss of power in certain movements at the shoulder joint, after all evidences of either dislocation or fracture have disappeared. An *x*-ray picture will show that the tubercle of the affected bone stands above and to the outside of its normal position, as determined by comparison with the healthy side, so that it must approximate to the acromion process before the abducted arm reaches the shoulder level. This removal of the normal position of the site of attachment of the supraspinatus, and the associated atrophy thereof, render it impossible for this muscle to overcome the obstacle interposed by the conditions stated; hence the impairment of movement at the joint.

Trigger Finger.—Five cases are reported by Dr. Tilman. All complained of difficulty in using the hand and of pain running up the arm. It is noteworthy that in all the condition seemed to result from over-use of the hand in doing work to which the patients were not accustomed. Examination showed in all circumscribed thickening of the flexor tendon of the finger affected. For treatment of a recent case the author advises fixation in extension upon a splint, daily changing of the bandage, applications of tincture of iodine, and massage. In older cases, if the finger is not too painful, passive manipulation is advised. In other more obstinate cases operative intervention is necessary. Gout and rheumatism may cause this peculiar tendon affection.

The Quantity of Diphtheria Antitoxin Required in the Treatment of Diphtheria.—William H. Park says that in diphtheria we should give enough antitoxin to neutralize all the toxin present and that likely to be produced at the seat of inflammation, and also whatever may have been absorbed. The tissue changes already produced we cannot hope to remove, neither can we hope to neutralize the poisons of the other bacteria which are so often associated with the diphtheria bacilli in the disease. From the results of experiments and from his observation of cases in hospital and private practice, the author has been led to adopt the following dosage. Very mild cases, 1,000 to 1,500 units for the first dose; moderately severe cases, 2,000 to 3,000 units; very severe cases, 4,000 to 5,000 units; laryngeal cases, according to their severity, 2,000 to 5,000 units. For children under one year he gives about one-third less than for older children and adults. He believes that the condition of the throat as to swelling, extent and nature of the membrane, etc., is a better guide to antitoxin dosage than the general condition of the patient. The duration of the disease influences the curative power of the antitoxin, rather than the dosage. If after twelve hours inflammation advances, or after eighteen hours it has not begun to subside, a second dose of antitoxin should be injected. In a very few cases a third dose is required at the end of thirty-four to thirty-six hours. For the bronchopneumonia and sepsis complicating some of the worst cases antitoxin is usually of no avail.

Cough in Influenza Simulating Whooping-Cough.—F. Forchheimer describes a cough following influenza, which possessed the following peculiarities. It always moved in epidemics and was decidedly contagious; previous attacks of whooping-cough were no protection. The onset was that of ordinary influenza, and the cough, which followed in a few days, was like that of pertussis, except that the whoop, while distinct, was not usually quite so marked. It was accompanied by congestive symptoms and followed by vomiting and expectoration. The blue color of the mucous membrane and tongue was absent, but ulcers of the frenulum were marked. If left to itself the trouble lasted from six to eight weeks, but in the majority of cases it could be aborted—so as to last a week or ten days only. Full doses of quinine form the best treatment, but must be large—not less than one decigram less than the age in years, and one centigram less than the age in months. When the cough has thoroughly developed, phenacetin or antipyrin give great relief, and in bad cases codeine and chloral may have to be administered.

Malarial Coma in Children.—George N. Acker reports two cases of coma connected with malarial fever, which he believes to have been due to the malarial parasite. Both patients recovered. The author says that it is remarkable that malaria in children does not cause more disturbance of the nervous system than is usually the case, for with the unstable condition that is found in poorly nourished children one would expect the cerebro-spinal system to be chiefly affected, resulting in paroxysms characterized by delirium, convulsions, coma, and tetanic spasms, producing serious disturbance of the functions of animal life.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE NEW BOROUGHS AND PUBLIC HEALTH—WAR NOTES—LISTER AT KING'S—EFFECT OF WINDY LOCALITIES ON PHTHISIS—SARCOMA—APPENDICITIS, RELATION TO RHEUMATISM, PREVENTIVE OPERATIONS—MANGLES AND TYPHOID—PLAGUE, DIPHTHERIA—THE LATE MR. ANDERSON AND DR. ECCLES.

LONDON, November 2, 1900.

THE London vestries are no more. All were duly executed yesterday, and Londoners elected the members of the new metropolitan boroughs. It is devoutly to be hoped that the new corporations will avoid the errors of their predecessors and will give their attention to the problems of municipal government which affect the public health. What with a new Parliament and new boroughs we have had a full diet of electioneering lately, but in London there is an amazing amount of apathy. We cannot tell yet the effect of yesterday's elections, but there seems a distinct apprehension in many quarters that the voters have neglected to poll. If so, we may find that we have not entered on an era of sanitary improvement. Yet every one is hoping for something better than the old vestrydom. Even men who would not take the trouble to vote are wondering whether the water supply will be better or the rates raised.

The commissioners on the war hospitals have returned from South Africa and will take evidence here next week. Dr. Conan Doyle's book entitled "The Great Boer War"

is exciting some comment and contains much of his experience in the Langman Hospital.

Mr. Treves has also entered the list of writers on the war with "The Tale of a Field Hospital," giving an account of the one which accompanied the Ladysmith relief column. These two works thus give the experience of surgeons at several points of the South African campaign.

Lord Lister opened the new laboratories at King's College on Tuesday evening and said the occasion marked an important event in the higher education of the metropolis. Lectures alone, he declared, were not sufficient—practical instruction was necessary in the various sciences. He thought it a happy coincidence that this great addition to the college occurred as it entered on an enlarged career as a part of the new London University. He would himself have preferred a second or teaching university, but other counsels having prevailed he hoped all would co-operate for the common good.

The influence of wind, or rather windy localities, on phthisis was the subject of an elaborate communication to the Medical and Chirurgical Society by Dr. Gordon of Exeter. The paper was illustrated by tinted maps and the facts brought forward pointed to results which were not destitute of the element of surprise. Dr. Gordon's investigations were confined to Devonshire. Comparing the mortality of phthisis with the general death rate of rural districts of Devon, he found that the variations of soil could not account for the facts. Rainfall seemed more closely connected with prevalence of phthisis but he was driven to the conclusion that this relation was that of a common cause. That cause seemed to be exposure to the west and southwest winds. Places where the dwellings were well sheltered from these winds had an annual death rate from phthisis of 0.24 per 1,000. With imperfect shelter the rate rose to 0.57. Where the dwellings were fully exposed to west or southwest winds, or both, the rate was 1.34. Dr. Gordon did not think differences in sunshine, temperature, or purity of the air could account for the figures, but we have no means of accurately estimating their variations. He recalled that the late Dr. Haviland had directed attention to exposure to wind as a cause of increase of phthisis.

In the discussion on the paper several suggestions were made to account for the facts. Thus, Dr. Cayley remarked that in the Scilly Islands the climate was mild but the winds were very violent. He had noticed that the windows were small, and thought the excess of phthisis there might arise from the people shutting themselves up too closely at night. This view was supported by Sir D. Powell and to some degree by Sir W. Broadbent, who thought it was the force of the wind rather than its direction which proved injurious. This, of course, points in the same direction. Other speakers mentioned other factors, and mostly agreed that windiness is a contraindication for the situation of a sanatorium. Dr. Longstaff remarked that not merely the country around, but the state of the dwellings, the occupations of the inhabitants, and their other circumstances must be considered. There were copper and tin mines in some of the places included in the paper, the farmyards in others were notoriously ill-kept, and other indications of dirtiness were obvious. Violent winds might induce "chills," as well as lead people to shut themselves up too closely.

Sir H. Weber thought it very difficult to examine one alone of the numerous factors.

Dr. Gordon, in his reply, said he thought the west and southwest winds were injurious because they were the most violent, the wettest and the most prevalent in Devonshire—to which all his statements were confined.

Two interesting subjects occupied the attention of the Medical Society on the 22d ult. The first was unusual cases of sarcoma. Mr. Shield read notes of four such, and others were mentioned by Messrs. Turner, Black, Pope, Waterhouse, and Morgan (president). The last named referred to the rarity of suppuration in association with sarcoma, though some had been mentioned by previous speakers. He had seen a case in the region of the os calcis which at first simulated tuberculosis, and one of ulceration of the toe in which the inguinal glands subsequently became melanotic. He did not approve the routine administration of potassium iodide to patients with tumors. Mr. Shield also held that this medication should not be allowed to impair the chance of recovery by operation. The question of rise of temperature might well have been discussed. It does not seem to be regularly recorded, but there is a rise and it is likely to cause errors, for it closely resembles that of suppuration.

The other subject was the association of arthritis and appendicitis. Cases have been recorded by Dr. Sutherland and others in which one preceded the other, or the two were coincident, and some in which perityphlitis was relieved by salicylates. The similarity in structure of the tonsil and appendix vermiformis has also been supposed to point to similar pathological tendencies. Dr. Beverley Robinson has not been able to convince himself that the two are causally related, and, I think, many other observers are equally doubtful. Dr. Pointon, who introduced the subject, seemed in this position, and mentioned the researches of Piard upon metastatic suppurations in connection with appendicitis, and Akerman's experimental production of osteomyelitis in young rabbits by injecting pure cultures of the bacillus coli. The polyarthritis is therefore probably of a pyæmic rather than a rheumatic nature. This view commended itself to the president and several of the speakers.

Dr. Rolleston thought the structural analogy between the tonsil and appendix supported the idea that appendicitis might be of rheumatic origin. He thought the prejudice against this view was due to a fear lest operation should be delayed in consequence, and suggested that septic infection might be added to a case started by rheumatism. Some patients certainly recovered under salicylates—a treatment long employed by Dr. Cavafy—but he admitted he had not seen a case arise during rheumatic fever, nor definite joint mischief in the course of appendicitis.

Mr. Wallis questioned the rheumatic nature of appendicitis, but thought arthritis might be due to it, or, indeed, to septic matter absorbed from any ulceration in the lower bowel. Dr. Savill had seen a case of prolonged polyarthritis in which death occurred from perforated appendix, and the joint mischief seemed due to septic absorption from the appendix.

Dr. Cayley pointed out that the cases in which there seemed any association between the two diseases were but very few, though there seemed some relation between catarrhal colitis and rheumatic symptoms. Surgeon-Major Black thought an abscess round the appendix might lead to absorption of pus into the femoral sheath.

The appendix vermiformis has also been the subject of discussion at another society—the Harveian—where Mr. Mansell Moullin maintained the advisability of early operation in all cases of acute inflammation. By early operation he means what may be called preventive. In all severe cases he holds the question should be determined within thirty-six hours of the onset, and even this limit may have to be shortened in some cases. As it is impossible to determine at the beginning of severe cases which may wait, he adopts the general principle that when there is danger ahead it is wise to ascertain the exact condition of things by a simple exploratory operation. He thinks an incision one and a half inches long and the introduction of a finger sufficient for this. The pulse he considers the best guide when to operate. It is better, he said, to operate on all severe cases at first, for it is not possible to distinguish those which might wait awhile. This course is wiser than to allow those to die who will otherwise have septic peritonitis, in order to save others from an operation which will become necessary later on. Mr. Raymond Johnson rather supported this view, though he admitted that such practice would result in operations being done on patients who might recover without. Still the danger of the operation was very slight. He thought the incision proposed very small, and that there was some danger of disturbing adhesions round small collections of pus.

A vigilant medical officer of health has traced an outbreak of typhoid to an infected mangle—an additional terror of the laundry.

Diphtheria is rather on the increase, but typhoid is abating. A case of plague arrived in a steamship from the Philippines. The vessel was disinfected and every precaution taken. Glasgow is to be congratulated. No suspected cases occurred in the last month. Only eight convalescents remain in hospital and no contacts in the reception houses.

Mr. William Anderson, F.R.C.S., died on the 27th ult., aged fifty-seven years. He was surgeon to St. Thomas' Hospital and professor of anatomy in the Royal Academy. From 1873 to 1880 he was principal of the Naval Medical College of Japan. There he made a valuable collection of art treasures, which is now in the British Museum. On returning to London he settled down to steady work at his old school, where he was highly esteemed as a surgeon, a colleague, teacher, and friend.

Dr. Symons Eccles died suddenly on the 22d ult. in his forty-sixth year. He served in the Russo-Turkish war and was decorated with the medjidieh. On returning he settled in London and devoted great attention to massage, his writings on that subject being of the best quality. He had been president of the West London Medical Society, and was one of the founders of the journal of the same name.

Dr. Ramon y Cajal.—The Spanish government has appropriated 80,000 pesetas ($16,000) to establish and maintain a laboratory of biological research in Madrid under the direction of Dr. Ramon y Cajal.

Stated Meeting, November 15, 1900.

WILLIAM H. THOMSON, M.D., PRESIDENT.

Conjugation in the Asexual Cycle of the Malarial Parasite.—DR. JAMES EWING delivered the Wesley M. Carpenter Lecture, taking this for his topic. He said that in 1897 his attention had been attracted by a specimen of blood from a recent tertian infection, in which there were numerous twin parasites of a few hours' growth. The evidence favoring conjugation of parasites rested principally upon morphological appearances. In many instances the young organisms were entirely separate. Many red cells contained two young parasites which were clearly fused together along the segments of their bodies, and two chromatin granules were found at different points. The bodies of these twin parasites apparently became fused together while their nuclei remained separate. Occasionally the two chromatin granules were closer together, but no fusion was observed at this early stage. Later on, a number of long budding pseudopodia might be seen. The chromatin masses were then subdivided into ten or twelve masses, but still remained far apart. Finally, the chromatin granules came to lie side by side surrounded by a milky or achromatic substance. Very numerous young twin parasites were succeeded by single forms, and a full-grown brood, all single, was found associated with a young brood consisting all of twins. The suggestion naturally arose, that the presence of two masses of chromatin did not necessarily mean the presence of two parasites in one red cell. It must be admitted that this objection was partially valid. However, he had never seen in the delicate tertian ring two equal chromatin granules. The significance of these double granules was not quite clear. The accessory granule might arise from incomplete fusion, or from precocious subdivision of the chromatin, or more likely by incomplete separation of the bodies of two spores. This he believed to be the mode of origin of some of the small "compact bodies" with more than one chromatin granule. In some of the conjugated forms three masses of chromatin granules were found, while only two bodies were found in the red cell. It might be objected that it was impossible to determine when the bodies of two parasites were united, as one might overlap the other and so give an appearance which would mislead the observer. Examples of twin parasites of advanced development were sometimes seen in severe tertian infection without subsequent conjugation. This was a rather common observation. He had seen hundreds of conjugating forms in a few months but only three or four twin parasites in as many years. Conjugation seemed to require the presence of a compact body and of a ring-shaped parasite. In some instances of multiple infection by full-grown malarial parasites there was evidence of death of one of the parasites. In his own cases showing conjugation no cases of dwarfed parasites could be found, and while young twins were quite common all the other older parasites were single. The usual result of twinning of tertian parasites was conjugation. Twins sometimes went to maturity without twinning, apparently when both parasites showed the usual ring form. As to the frequency with which conjugation occurred, the speaker said that the majority of specimens failed to show distinct traces of the process, although he had found little difficulty in obtaining specimens showing a few conjugating forms. These specimens were all taken from very rich infections. The conjugating forms were usually few or wanting when the number of parasites was small, or when quinine had been given. Single parasites of both types—the compact bodies and the thin rings—could be traced through the later stages of their development. In the full-grown stage of the compact bodies they still contained numerous chromatin granules. As the thin ring forms increased in size they were characterized by their hyaline appearance and tendency to stain with methylene blue. In the full-grown stage it was exceedingly difficult to demonstrate the chromatin. The crescents of the æstivo-autumnal forms had been long divided into two kinds, viz., the small flagellating or male body, and a larger and more densely staining or female body. He had been unable to trace the development of the two forms of æstivo-autumnal rings that he had described. If conjugation occurred in this parasite, it probably lasted for only a brief period, and could be demonstrated only in peripheral blood in which these bodies were closely massed. It was a well-recognized biological principle that conjugation among protozoa might be the only sexual feature of reproduction during a limited number of generations, after which the sexual capacity ceased, and must be redeveloped by the formation of new bisexual forms. The spontaneous disappearance of the malarial infection might be explained by a gradual failure to reproduce by conjugation, and the development of single parasites into individuals sterile for the human host, but adapted for development in the mosquito. The malarial parasite might be said to begin its existence in the human host by a series of development of amœboid bodies. Later on the sexes became fully differentiated, as shown by the formation of the flagellated and non-flagellated bodies. These forms were sterile to the human host, but fertilization might take place in the mosquito. Here the parasites became encysted, but subsequently in some way germinal rods were formed, and were eventually introduced into the human body as amœboid forms.

SECTION ON SURGERY.

Stated Meeting, November 12, 1900.

CHARLES N. DOWD, M.D., CHAIRMAN.

Intra-Abdominal Omental Torsion.—DR. JOSEPH WIENER presented a man seventy-nine years of age, upon whom he had successfully operated for the removal of an intra-abdominal omental tumor. Owing to the patient's bad condition at the time of operation, nitrous oxide gas had been used for the anæsthetic. The history had pointed to an appendicitis, but the latter had been excluded at the operation. At the site of the tumor that had been detected on palpation was a piece of omentum which had been subjected to torsion. It was of a dark blue color. The adhesions were tied off, the pedicle was untwisted, and the abdominal wound was closed. The patient had made a good recovery.

Gibson's Method of Suprapubic Drainage of the Bladder.—DR. P. R. BOLTON presented a man who had been referred to him last summer by Dr. McIntyre. He had a calculus in the bladder. The bladder had been exposed by an incision through the recti, then opened, and the calculus extracted. The bladder had then been sutured in the angles of the incision, taking only the muscular layer. The bladder was anchored securely to the posterior surface of the recti muscle. A drainage tube was securely fastened in by sutures. On the fifth day the sutures had been removed, and the man had been discharged on the following day. The method had worked admirably, having completely prevented any leakage from the bladder.

Perineal Prostatectomy.—Dr. Parker Syms presented a man sixty-eight years of age, who had been admitted to the Lebanon Hospital on November 20, 1899. For several months previously there had been frequent micturition, and at the time of his admission complete retention of urine. Examination had shown a large prostate but no cystitis. A median incision had been made in the perineum, and the prostate enucleated. The bladder had been drained through the perineum for a few days. The man was now able to hold his urine for four or five hours. The speaker said that he was desirous of doing prostatectomy without making a suprapubic opening, and to facilitate this had devised a special drainage instrument, a sketch of which was shown.

Dr. Wiener said that he had carefully studied the reported cases of omental torsion, and had come to the conclusion that the formation of a pedicle might be explained by the fact that at one time a portion of the omentum had been in a hernial sac, thus allowing the distal portion to become thick, and by pulling on the rest of the omentum tended to the formation of a pedicle.

Dr. L. Bolton Bangs commented favorably upon the method of suprapubic drainage devised by Dr. Gibson. He had had an opportunity of trying it in only one case, that of an old man in bad condition. He had opened the bladder and removed twenty-six faceted stones. He had inserted two rows of sutures, and this had prevented all leakage.

Dr. Willy Meyer said that the case presented showed what could be done by this method, but there was a possibility that this unfolding of the bladder might unduly reduce its capacity.

Dr. Bolton replied that in his case there had been no evidence of reduction in the capacity of the bladder, for the patient had been able to sleep all night and urinated only three or four times a day.

Hernia and Obscure Abdominal Pain.—Dr. William H. Thomson said that some years ago Mr. Bennett, of London, had delivered a lecture on certain obscure abdominal pains. He had pointed out that such pains were sometimes due to small omental herniæ in the walls of the abdomen, and having no connection whatever with the inguinal canals. Soon after, the speaker said, he had met with just such a case. The pain had developed in a man after a sudden misstep on the sidewalk. The inguinal canals were perfectly free, but about half-way between the symphysis and the umbilicus there was a tender spot, and operation had proved this to be a hernia. The operation had given relief. Another case had been seen shortly afterward. Last May he had seen a third case. The patient, a woman, had fallen across a pipe railing, and had broken two ribs. After the ribs had healed there was a continuous, dragging, severe pain. Examination had shown simply a small tender spot two inches to the left of the umbilicus and nearly three inches above this level. Palpation had failed to detect any tumor, and a surgeon had made an exploratory incision under local anæsthesia. A small knuckle of omentum had been found caught in the rent in the abdominal wall.

Heat Stroke as a Post-Operative Complication.—Dr. Charles L. Gibson said that in this city during the heated term a combination of heat and humidity with absence of breeze was very liable to lead to heat stroke. He had become deeply impressed with heat prostration as a factor in causing fever and other constitutional disturbance after operation. Of course, one must be cautious about attributing to heat stroke many disturbances which might perhaps be the result of sepsis, iodoform poisoning, or other causes. The first case reported was that of a boy admitted with gangrenous appendicitis. The operation had not been complicated and the boy had reacted well, but on the following day had developed a temperature of 104° F. and a pulse of 148. This had been associated with delirium and with other symptoms which seemed to point to a speedily fatal termination. By cold sponging the temperature had been quickly lowered to 100.6° F., and with this change in temperature the pulse had dropped to 98 and had become of good quality, and the delirium had subsided. After this recovery had been uninterrupted. The weather at the time was very hot and sultry. A second case occurred on August 10th, one of the most trying days in the hospital operating-room during the past summer. By bearing in mind the possibility of the occurrence of such a complication, the appropriate treatment was more apt to be instituted and preventive measures were likely to be employed, such as securing good ventilation by electric fans or other means.

Dr. A. B. Johnson spoke of a case on which he had operated last summer when the temperature in the operating-room had been about 102° F. The patient was a child having a small scar on the lower lip. The child was apparently in perfect health. A very small quantity of chloroform had been administered, the scar cut out, and a single skin graft applied. So trivial was the operation that one might have been justified in doing it in a physician's office. Within a few hours after the child had been returned to the ward the temperature had reached 108° F. He had not recognized the possibility of this condition being due to heat stroke, and consequently refrigeration had not been resorted to. The child had died that night. Within a few days after this he had encountered two similar cases, and all the other probable causes of such fever had been carefully excluded. These cases had both yielded promptly to cold sponging. Looking back over the years past he could not but feel that he had seen several other cases explicable on the theory of heat stroke. He remembered particularly a group of three cases, all operated upon in extremely hot and sultry weather, and all terminating fatally.

Dr. George E. Brewer said that on July 4th he had had occasion to operate upon a youth of nineteen for sarcoma of the tonsil and soft palate. The operation had been a severe one, but the patient had left the table in excellent condition. The thermometer in the operating-room on that day had registered 99° F. Within two hours after being returned to the ward the house surgeon had reported that the man appeared to be dying. The pulse was 150 and the temperature 105° F., and he was extremely restless and delirious. Some hours later, on mentioning this case to Dr. Gibson, the suggestion had been made by the latter that this was a case of heat prostration. The treatment outlined in the paper had at once been undertaken, with the result that there had been immediate improvement. It had been several days before the temperature and pulse had returned to the normal, but the effect of the refrigerating treatment had been immediate and most marked. This was the only case that he had seen in which the symptoms had been characteristic, and he had felt that other causes could be excluded. Since that time he had seen heat stroke in one of Dr. Weir's cases. He was very glad that this topic had been presented for discussion, for he felt confident that this complication of heat stroke was a reality.

Dr. Robert T. Morris said that it would be most interesting to study in this connection the anæsthetics employed in these cases. He believed a large proportion of the cases of sunstroke occurred in alcoholic persons, and after they had indulged quite freely in alcoholic drinks. It was possible that the anæsthetic agents acted somewhat like alcohol, rendering the system less resistant to heat. He recalled an experience

of two years ago, in which there had been several high temperatures immediately following operation, occurring during a period of hot, moist weather. He had made a mental note of it at the time, but was exceedingly glad that the attention of the profession had been directed to this subject by this paper.

Dr. James P. Tuttle said that he had seen several very high post-operative temperatures during the summer, and had been unable to explain them before hearing this paper. One of these cases had occurred last summer, and had terminated fatally. In this case the temperature had risen to 107° F. and had reached 109 at the time of death. Owing to suppression of the urine it had been supposed that the kidneys had been responsible for this death, but the autopsy had failed to substantiate this view. Chloroform had been the anæsthetic employed.

Dr. A. V. Moschcowitz said that during the past summer he had performed an amputation of the lower extremity in a case of Raynaud's disease with gangrene. In three hours after operation the temperature had been 107° F.; in another hour it had reached 109°, and in five hours death had occurred. Before this a diagnosis of heat stroke had been made. Although a most exhaustive and painstaking autopsy had been made it had shown only hyperæmia of the meninges, and a turgidity of all the blood-vessels of the brain. In another case a prompt resort to refrigeration had brought down the temperature and the patient had made a good recovery.

Dr. William H. Thomson said he would like to know whether any of those present could recall having seen similar cases in cool weather.

Dr. Alexander Lambert said that the cases cited this evening reminded him very strongly of some of those cases of heat stroke seen by him at Bellevue Hospital during the very hot weather of 1896. The rapidity with which the temperature had risen after these operations would seem to be sufficient to exclude septicæmia or even kidney complication. He had often wondered why there were not some cases of heat stroke when he had seen the way in which many operative cases were swathed in cloths, and towels, and thick dressings. The most important meteorological factor in the production of heat stroke was lack of motion of the air, and the consequent interference with radiation of heat from the body. In that dreadful hot season in the summer of 1896, the wind did not for ten days move faster than six or eight miles an hour. This memorable period was marked by less than the average humidity, and yet the number of cases of heat stroke was appalling. He could not agree with Dr. Moschcowitz that turgidity of the cerebral vessels indicated heat stroke; there was nothing indicative of heat stroke except the changes in the nerve cells. One of the best methods of controlling the high temperature in heat stroke was by the administration of ice-water enemata.

Dr. Studdiford reported a case operated upon in July about 9:30 A.M. The case was one of fibroid and pus tubes with total hysterectomy. At 1 P.M. the temperature had been 102° F.; at 8 P.M. 103.6°, and the following morning 102°. In the evening it had reached 106°, and a little later 107.6° F. The case had not been looked upon as one of sepsis, and had been given an ice-pack. By nine o'clock the temperature had fallen to 101.6°, and by 9 A.M. to 98.6°. There had been nothing about the wound or the vaginal drainage to indicate sepsis. The patient made a good recovery.

Remarks upon the Construction of Amputation Stumps, with a Report of Two Cases of Amputation by the Osteoplastic Method of Bier.—Dr. A. V. Moschcowitz read this paper. He said that most of the really satisfactory amputation stumps had followed disarticulations or amputations near a large joint. At one time the volume and thickness of stumps were considered to determine their usefulness, but every one had seen stumps made of broad bony surfaces which were not at all serviceable. There could be no question, he thought, about the superiority of Bier's osteoplastic method, although it necessarily lengthened the operation somewhat, and hence might not be appropriate in certain cases. The technique differed from ordinary methods in the formation of an osteoplastic flap. As it was difficult to make this flap with an ordinary saw, he had devised a special saw for this purpose. Taking the leg as an illustration, the periosteum of the anterior surface of the tibia was circumcised on three sides of the quadrilateral space, the edges of the periosteum were raised for a short distance from the bone, and a thin plate of bone was sawn out. This was used as a cover to the sawn edges of bone, to which it united, giving a useful bearing surface for the stump, and one free from tenderness. A skiagraph taken eighteen days after one of these amputations of the leg showed perfect union between the osteoplastic flap and the tibia, but not between this flap and the fibula. The speaker said that since he had become interested in this subject he had embraced every opportunity to examine amputation stumps of all kinds, and had been able to satisfy himself of the fact that every stump made by other methods, unless the result of a disarticulation, was more or less painful. Bier claimed that his method was an absolute prevention of conical stump.

THE NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 10, 1900.

Eugene Hodenpyl, M.D., President.

Sarcomatosis of the Peritoneum.—Dr. F. C. Wood presented several specimens. The first of these was one of sarcomatosis of the peritoneum, removed from a small Chinese woman who was very much emaciated. An exploratory operation had been done, and she had died soon afterward. The autopsy revealed the mass presented. The determination of the primary growth was especially difficult in this case because nearly all of the abdominal organs were involved. The spleen had escaped. There were no metastases anywhere in the body. Presumably the growth had originated from the retroperitoneal lymph nodes, but microscopical examination of the tumor was rather against this, for the appearance presented was that of a sarcoma consisting of round and spindle cells. The specimen under the microscope showed an extreme degree of fatty degeneration. The right ovary could not be found, so that possibly the growth might have started from that ovary. The uterus was not invaded. The bladder wall had been invaded, and was about one inch in thickness. The woman claimed to have been in perfect health up to five months before admission to the hospital, and stated that there had been no evidence of the tumor previously.

Diffuse Lympho-Sarcoma of Both Kidneys.—The pancreas, liver, uterus, and ovaries were involved in this case. The specimens had been removed from a woman twenty-six years of age, who had always been an invalid. About one year and a half before admission to the hospital she had begun to have considerable pain in the abdomen, and about the same time had noticed some enlargement of the abdomen. The urine had been examined repeatedly for a long time by a competent physician, but with negative result,

although it was assumed that the kidney was the seat of a new growth. On admission, there was an oval tumor in each flank. The urinary examinations in the hospital had also been negative. The blood examination showed moderate leucocytosis. The woman had died from shock the day after an exploratory laparatomy. The kidneys presented suggested fœtal lobulation. When fresh, the tubular markings had shown pretty well, and portions of the kidney tissue seemed good on gross examination. Microscopical examination, however, showed that the kidney tubules were separated from one another by a layer of small round cells. One of the kidneys presented weighed one pound and nine ounces, and the other, one pound and four ounces. In this case the pancreas was large and quite firm, and microscopical sections showed infiltration of lymphoid cells into the trabeculæ. The ovaries were completely infiltrated, as was also the uterus. A large ragged ulcer, about three inches long, was situated in the ileum just above the caput coli, and extended around the entire circumference of the gut. There was nothing in the history pointing to such a condition. Sections of the ulcer showed nothing but necrotic tissue extending down in portions to the peritoneum. No tubercle bacilli were found, so that the cause of the ulcer was still in doubt. The spleen was perfectly normal, both in size and structure. The question naturally arose, Did not this patient have a simple pseudo-leukæmia? He believed one case of lymphatic leukæmia without enlargement of the spleen had been reported, yet the general findings had not been those usually present in lymphatic leukæmia. He would, therefore, classify the infiltration in the case just presented as one of diffuse lympho-sarcoma. Sections of the kidney were exhibited under the microscope.

Accessory Lobe of the Liver.—A specimen was shown by Dr. Wood. There had been a congenital atrophy of a portion of liver tissue, thereby cutting off a segment. The patient had entered the hospital with pain in the abdomen and a high temperature. Physical examination of the chest had revealed a pneumonia. As there were jaundice and abdominal pain, cholelithiasis had been diagnosed. Palpation showed a mass thought to be the gall bladder, but this proved at autopsy to be an accessory lobe of the liver. Death had resulted from pneumonia.

Cirrhosis of the Liver.—In this case there were several adhesions between the anterior abdominal wall and the omentum, containing several large veins. The diaphragm was likewise adherent to the liver. The veins running from the liver to the umbilicus were also enlarged. The man was about fifty-five years of age, and up to three weeks before admission had been able to work. Nevertheless, the autopsy had shown advanced cirrhosis and advanced change in the portal circulation. The explanation probably was to be found in the existence of a complete collateral circulation. The operative cases in which a collateral circulation had been established had usually been relieved for a number of years. This operation consisted in stitching the omentum to the abdominal wall, and thereby short-circuiting the portal circulation into the general circulation and reducing the pressure in the portal system.

Metastatic Epithelioma in the Heart.—Regarding this case the speaker said that the peculiar feature was that there were no other metastases in any part of the body. The patient was a man who had previously had the tongue removed for epithelioma. The tumor had recurred in the supraclavicular lymphatic nodes, and death had finally resulted from pressure on the trachea. The autopsy had revealed infiltration of the tissues of the neck and involvement of the lymph nodes in the anterior mediastinum. Examination of the heart showed metastases deep in the muscle, and also superficially in the fat on the line of the vessels. They were probably embolic in origin. This condition of the heart had given rise to no symptoms.

Dr. L. A. Conner said that he had been deeply interested in the diffuse sarcoma of both kidneys. He had not realized before that it was possible for such a growth of sarcoma to involve the kidney and still the markings to be preserved so well. This fact led him to suspect that there might be some other explanation.

Dr. Wood replied that the picture under the microscope showed plainly that the cells had infiltrated the spaces between the tubules, and left a fairly good tissue between. The same thing was seen sometimes in cases of nephritis and also in the involvement of other organs. He did not assume that the tumor was primary in the kidneys.

Dr. E. Libman said that last spring he had presented some cases of sarcoma of the intestine. In one of these the kidneys had been infiltrated in exactly the same manner, as shown by both gross and microscopical examination.

A Case of Pulmonary Stenosis due to Ulcerative Endocarditis of Aortic Valve.—Dr. E. Libman presented this case. The patient was a man twenty-one years of age, who had been well up to May, 1897, when he had suddenly lost the sight of the right eye. He had recovered, some weeks later, sufficiently to be able to read large letters. Three months afterward he had lost the power of speech for twelve hours. On October 26, 1897, while sitting in a chair he had become paralyzed on the left side and totally unconscious. On admission to the Mount Sinai Hospital the following day he was found to be hemiplegic and unconscious. The left ventricle was distinctly hypertrophied. There was a rough, blowing systolic murmur at the apex, transmitted slightly to the left. There was a very loud systolic murmur over the aortic valve, which was transmitted upward and downward, and accompanied by a very marked thrill in both the carotids and subclavian veins. There was no elevation of temperature at this time, but about two weeks later he developed a fever, and this continued up to the time of his death. Six days before death a blood culture (blood from vein) showed the presence of the staphylococcus albus. Two days before death a systolic murmur and thrill developed in the pulmonary region, and were entirely distinct from those in the aortic region. The second pulmonic sound did not diminish in intensity. The clinical diagnosis was ulcerative endocarditis of the aortic and pulmonary valves successively. Petechiæ developed over the body. A culture from the heart's blood made directly post mortem after burning the skin also showed the staphylococcus albus. The post-mortem showed the right ventricle very markedly hypertrophied. The aortic valve was ulcerated, and in the free edge of two of the flaps and part of the third there were large vegetations. The sinuses of Valsalva were filled with vegetations. In the interventricular septum back of the aortic valve there was an enormous hemorrhagic swelling, which almost entirely occluded the pulmonary artery. Cultures from the vegetations and the centre of the swelling showed the staphylococcus albus. Spreads from the soft, purulent centre of the swelling showed numerous staphylococci.

Dr. G. Langmann said that all these or similar cases were mostly classified under the name of aneurism of the heart wall or septum, although they surely did not form a true aneurism. Their origin was justly attributed to an infection of the heart wall continuously hit by the infected valve.

Dr. Libman replied that the stenosis had been due to the aortic endocarditis, as the latter had caused an enormous inflammatory swelling in the septum.

Dr. James Ewing asked what significance was attached to the presence in these cultures of the staphylococcus albus. It seemed to him this might have been an accidental germ in the circulation, or the specific cause of the endocardial lesion, or possibly a contamination of the culture. It was also possibly the result of an ante-mortem invasion of the blood by these germs.

Dr. Libman said that there was an old endocarditis. Out of one hundred and fifty blood cultures he had never met with the staphylococcus albus as a contamination. From the technique employed, both during life and at the autopsy, he felt positive that the staphylococcus albus was the specific cause. Furthermore, he had found bacteria in the blood (intra vitam) in fatal cases of ulcerative endocarditis, whenever cultures had been made.

Dr. Conner said that two or three years ago he had presented an aneurism involving one of the sinuses of Valsalva, and producing a bulging forward of the conus of the pulmonary artery, and causing a very marked pulmonary stenosis, in which the appearances were strikingly similar to those of the present case. There appeared in the specimen just presented also to be a laminated clot.

Dr. Libman said that the examination seemed to show that this was a developing abscess of the heart muscle.

Effects of Repeated Intubation.—Dr. David Bovaird made some remarks on this subject, and presented illustrative specimens. He said that in some instances it was necessary to practise intubation repeatedly on the same person. In one case occurring under his observation, a child had been intubated forty times, yet had recovered. The first specimen presented had been taken from a child about three years of age, who had been suddenly seized with croupy cough and severe dyspnœa. Antitoxin had been given promptly, and intubation done almost immediately afterward. A few days after the tube had been removed, but recurring stenosis had required intubation again. While the tube was still in place, the child had developed measles and then pneumonia, and had died as a result of these complications. At the autopsy there had been found at the base of the epiglottis an ulcer of considerable size. In the body of the larynx, just within the cricoid ring was a large and deep ulcer. This ulcer involved the cricoid cartilage, severing it completely in front. Farther down in the larynx and near the trachea were two small ulcers corresponding to the lower end of the intubation tube. The ulcer at the base of the epiglottis represented the pressure made by the head of this tube. The ulcer at the cricoid cartilage was the result of the pressure of the body of the tube. The second specimen had been taken from a child aged six months. This child while recovering from measles had developed stenosis. A tube for a one-year-old child had been inserted, and the child had done well until the removal of the tube at the end of five days. Intubation had been required at the end of twenty-four hours, and this had to be repeated every two days for several days, and then almost constant re-intubation had been demanded because the child kept coughing out the tube. For this reason a tube for a two-year-old had been inserted, with like result. A tube for a three-year-old had then been introduced. This specimen showed large and deep ulcers at the base of the epiglottis. Nothing could be found representing the cricoid cartilage, it having apparently been absorbed by reason of pressure. There were three ulcers corresponding to the points of pressure of the lower end of the tube. In both specimens it was interesting to note the amount of injury done to the cricoid cartilage. As this cartilage was not only a support for the larynx but the attachment of important muscles, it was evident that the destruction of this cartilage would be in itself sufficient to explain the recurrent stenosis of the larynx, the muscles by which the glottis might be opened no longer having a *point d'appui*.

Cystic Kidney.—Dr. Bovaird also presented a specimen of congenital cystic kidney removed from a child aged one year, dead of some enteric affection. The right kidney was the one involved. On the other side the pelvis of the kidney was found dilated and filled with gravel. There was also a stone of some size. These conditions on the left side suggested a possible explanation of the cystic degeneration on the right, that the ureter or pelvis of the kidney had been blocked by a stone and the cystic degeneration had resulted from the obstruction. No stone or gravel could, however, be found on the right side.

Dr. W. P. Northrup said that these two cases, following closely after measles, suggested the explanation of the tissues breaking down so easily. These cases of so-called "retained intubation tube" were both of comparatively short duration. One should bear in mind the behavior of measles in a children's institution. Such children got up pressure necrosis on the back of the head, cancrum oris, necrotic processes on the fingers, and pressure sores on various parts of the body. Their tissues had diminished resisting-power. As regarded the prolonged retention of intubation tubes, a case had just been reported in the *Archives of Pediatrics*, October, 1900, p. 737. In this case there had been subglottic stenosis, and after repeated intubations and extubations in the hands of a novice, the tissues had been denuded and had then grown together. Ultimately a tracheotomy had been required, and the child had died from pneumonia after this last operation. In this case the larynx had presented distinct hour-glass constriction, and complete atresia.

Photomicrographs of Filaria Sanguinis Made with a Special Lens.—Dr. Buxton exhibited a series of photographs taken with a one-tenth Spencer lens from specimens mounted in balsam and examined through α-brom-naphthalene instead of oil of cedar, as recommended by Dr. Piffard. Certain new striations appeared in some of the photographs taken with this lens.

Dr. Ewing said that the method employed had developed in the body of the filaria a peculiar cross striation, which was evidently part of the structure of the capsule of the filaria. So far as he knew it had not been described before, and certainly had not been observed in any previous drawing or photomicrograph.

Effects of Milk Preserved by Formalin upon Mice and Kittens.—Dr. William H. Park read a paper with this title. He said that the addition of formaldehyde to milk made the proteid material somewhat less digestible. The proportion required to preserve milk was about 1 : 50,000, and in this quantity digestion might be retarded about ten per cent. It was not contended that the end products were different, only that the digestive process was retarded. Certain reported investigations seemed to leave in doubt the question of the effect of formaldehyde on small animals. In one series small gains in weight were noted in kittens and rabbits, and a slight loss in a guinea-pig only. Another investigator had used three or four kittens for each control, and had experimented with different proportions of formaldehyde. When 1 : 50,000 formaldehyde was used, one of the kittens died in the third, and two in the fourth week, while the other two gained in weight. Of four kittens getting 1 : 25,000 formaldehyde, all gained. Of five getting 1 : 12,500, two died in the fourth week, two gained, and one lost. All the control kittens were reported to have gained—certainly a very remarkable showing. It had

been stated that 1:50,000 retarded the increase in weight twenty-nine per cent., and 1:12,500 sixty-nine per cent. These statistics had been manipulated in such a way as to leave grave doubts as to their reliability. Dr. Park said that he had accordingly experimented with young white rats, using 1:50,000, 1:10,000, and 1:1,000 solutions of formalin. All of the rats had gained in weight and at very nearly the same rate. A series of experiments had then been undertaken with cats, using pure milk, milk containing 1:10,000, and milk containing 1:1,000 formalin. At first they were fed on pure, selected milk. They all gained on this, but the 1:1,000 much less than the 1:10,000, 1:50,000, or pure milk series. Later on changing to ordinary milk the cats lost weight, except those fed on milk containing 1:10,000 formalin. The explanation probably was that the ordinary milk in the hot weather (August) fermented through the night in the feeding-dishes, except the milk containing 1:10.000 or more formalin. Ordinary store milk in summer contained not only great numbers of bacteria, but also the products of their growth. He was inclined to think that among the poor, who could not keep the milk properly cold and sweet, it might be well during the hot months to introduce into the milk a small quantity of formalin, or if possible a better preservative, and label such milk "preserved milk," because it would do less harm in the milk than the products of fermentation.

Dr. Northrup thought the question propounded by Dr. Park could have but one answer. If the formalin only retarded digestion, then it would certainly be better to feed this to children than to give them milk containing a large quantity of bacteria and all sorts of by-products. If it were simply formalin delaying slightly digestion, against milk containing bacteria plus the never-to-be-forgotten toxins incidental to such growth, the answer was in favor of the lesser poison, namely, formalin. The great trouble was to accomplish this without opening the way for many abuses.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, October 2, 1900.

J. Arthur Booth, M.D., Chairman pro tem.

Periodical Psychoses.—Dr. A. B. Defendorf read this paper. He said that years ago all forms of insanity were looked upon as more or less periodical, but gradually this list had been reduced to periodical mania and periodical melancholia. The English and American observers had been slow to recognize periodical insanity. The records of hospitals for the insane showed it to constitute a not inconsiderable percentage of cases admitted, coming second to dementia precox. These cases were characterized by intense psychomotor restlessness, yet they exhibited no signs of fatigue after weeks or months of excessive motion. One of the striking features of this form was that consciousness continued unclouded. In the extreme maniacal condition called delirious mania the patient's consciousness of surroundings did become clouded. These patients were rich in words if not in ideas. Delusions when present were transitory, and were usually of the expansive type. They were happy and contented, yet they changed very suddenly from happiness to melancholia or *vice versa*. In the depressive form the associations of ideas showed retardation, and the emotional attitude was uniformly one of depression or despair. More or less stable delusions were present. Cases would be found showing both the maniacal and depressive elements, but usually one or the other predominated. The most prominent etiological factor was defective heredity, it being found in from seventy to eighty per cent. Other causes were shock, acute diseases, and mental strain. When the first attack occurred after childbirth it was apt to recur with each succeeding confinement, and continue after the climacteric. The first attack was apt to be of the depressive form. More than half of the cases occurred before the age of twenty-five. As the attacks were repeated, the lucid intervals tended to shorten. During these intervals the mental faculties were fully retained. The prognosis of the psychoses was bad. During the height of the disease or in the extremely maniacal or depressive forms, death might occur from exhaustion, or might be self-inflicted. The author's conclusions were: (1) Periodical insanity was characterized by a definite symptomatology, which permitted of differentiation in the first attack; (2) it was a prominent psychosis.

Dr. B. Sachs said that while all recognized that there was such a thing as periodical insanity, there was danger lurking in the term, because almost all forms of mental phenomena were apt to exhibit a tendency to recurrence. For this reason it should be insisted that there must be a regular recurrence; for instance, of mania and depression with perhaps a lucid interval. It was rather curious that those describing periodical insanity insisted that there must be marked depression. He could recall a case of distinct hypochondriasis followed by a lucid interval of seven years and then an attack of pronounced melancholia. There was again a lucid interval followed by an attack of mania. Attention was called to the remarkable suddenness with which the patient passed from one state to another. He had had under observation a girl who had been in a state of depression for over eight months, and then very suddenly had had a lucid interval lasting one year. This had in turn been followed by acute mania.

Dr. W. D. Granger said that a few cases of undoubted circular insanity were so decided in their symptoms that they could not be mistaken for anything else. This was particularly true if the person was seen late in life, and had a history of recurrent attacks extending over many years. There were, however, many cases less pronounced in type, rendering it difficult to classify them. He had personally seen only a few cases of circular insanity. He had never seen the sudden changes referred to by the last speaker, nor had he ever seen a case of true incoherence in connection with circular insanity. He had seen several cases of recurrent insanity in which there would be from two to five attacks of rather mild melancholia. He had had a young lady suffering from this form of insanity, and also her mother, brother, and sister. The sister had had a most violent mania, proved at autopsy to have been a complication of typhoid fever. She had had periodical attacks of active though not violent mania. Another form of the circular type that he had noticed and had never seen described in the text-books was the form of chronic mania developing in the last few years of life recurrent attacks of mania and melancholia.

Dr. William H. Thomson said that he had had under his continuous observation for ten years a case of periodical insanity, and probably the only one to which he would be willing to apply the term periodical insanity. The attacks had recurred regularly every other day all these years. The patient was a man forty-eight years of age when the disease had first set in. There was no hereditary psychosis. At the beginning he had been attacked with melancholia, and had attempted suicide. Attention had been early directed to the fact that his condition was worse every other day, and for this reason he had had most thor-

ough and persistent antimalarial treatment. When first seen by the speaker, his memory had been good, and he had been in no way irrational. The temperature had been normal. The next day his temperature had risen to 101° F., and he had become delirious. On the following day his condition was that noted at the first visit. The febrile symptoms had ceased after about three months, but in other respects the patient had kept up this alternation ever since that time. Examination of his secretions had thrown no light whatever on the etiology of his singular mental disturbance. The type was that of melancholia with excitement. He had never been truly maniacal. Regarding periodical psychoses in general, Dr. Thomson said he could not agree with the reader of the paper that they constituted such a definite class, for, if so, they should be definitely periodical. Another case was then cited, in which the attacks had begun with talkativeness and an appearance of well being, which would last for about six weeks, and would be followed by extreme mental depression. At no time was there any confusion of personality or any delusion. The attack of mental paresis would last two or three months, and would usually come on every winter. Such a case seemed to him a true example of periodical psychosis, but many of those described in the paper seemed to him to come rather under the head of relapsing than periodical insanity.

Dr. William M. Leszynsky said that no one could tell at the first attack whether there would be recurrence or not. With a good previous history it was an entirely different matter.

Dr. L Pierce Clark said that, while in a hospital for insane, he had seen a case of intermittent mental stupor which recurred at short and fairly regular intervals, thus resembling in some respects the case reported by Dr. Thomson. Such cases were very rare, only six being on record. Sudden transitions were quite characteristic in the mental disorder first described by Charcot in connection with mental epilepsy.

Dr. Defendorf said that the periodicity was the characteristic of the whole course of the disease throughout the life of the individual, and it was certainly an irregular periodicity. But there were certain fundamental symptoms, such as the condition of the memory, the tendency toward deterioration, and the character of the delusions and hallucinations, upon which the diagnosis should be founded. Relative to the sudden transitions from one state to another, he said that this occasionally happened, sometimes over night.

Status Epilepticus; its Nature and Pathology.—Drs. L. P. Clark and T. P. Prout presented this paper, Dr. Clark reading the clinical portion. About forty-five cases formed the basis of the paper. Unfortunately only five cases could be studied histopathologically. The modern notion of status, it was stated, was that it was the acme or true climax of the disease, and not, as formerly supposed, a chance termination of epilepsy that by proper treatment could have been avoided. It was a state of epilepsy in which one seizure followed another so closely that the previous psychical exhaustion was not recovered from. One patient at the Craig colony for epileptics had three hundred and eighty-four typical psychic seizures in one day. It occurred with about equal frequency in all the different forms of epilepsy except that dependent upon organic brain disease. The latter constituted one-half of all the cases of status. Exhaustion paralysis was very characteristic of status. No foundation had been discovered for the statements of some writers that either age or sex exerted any influence. According to the authors' experience, the shortest interval had been in those developing their epilepsy between the ages of ten and sixteen years. On an average, eleven years elapsed between the beginning of the epilepsy and the occurrence of status. Menstruation in women did not seem to be productive of status. In the great majority of cases the approach of status was denoted by a steady increase in the frequency of the epileptic seizures. They had seen three hundred attacks a day in several cases, and still recovery had occurred. One patient had had status epilepticus for twelve days, and had recovered, having had during this time eighteen hundred seizures. The temperature elevation in status usually began after the first severe convulsion, and there was usually a direct ratio between the number and severity of the convulsions and the elevation of temperature. The record of the pulse, temperature, and respiration frequency gave the best indication of the severity of the status. Generally the maximum of the fever marked the maximum of the seizures, and if the fever persisted after this, one should be led to suspect some complication. Occasionally the fever subsided by crisis. Occasionally also the temperature rose to 107 or 108 F. As to the cause of the fever curve, the paper stated that some looked upon the elevation of temperature as purely psychical, while others believed it was the result of a direct action on the heat centre. The pulse rate increased in frequency with each attack, but the pulse curve usually ran nearly parallel to the temperature curve, though responding more slowly on recovery from status. Almost always there was Cheyne-Stokes respiration, but it was not so unfavorable a symptom as in some other disorders. Both pneumonia and pleurisy were fairly frequent complications. The prognosis of status was necessarily grave. A low temperature was supposed to be a fair sign, though there might be recovery after a temperature of 107.5° F. Paralysis of the muscles of deglutition was a very unfavorable sign. The gradual, steady increase in the symptoms was the most unfavorable sign of all. Many patients had a record of two to five status periods, and it was probable that the mortality did not exceed twenty-five per cent. It was possible to abort a case of status, if taken in time, and certainly the present mortality should be reduced. The plan of treatment pursued in the cases mentioned in the paper was as follows. At the outset the patient was given a dose composed of gr. xxv. of bromide, gr. xx. of chloral, and a large dose of opium and morphine. If the convulsions were not controlled, gr. xxx. or xl. of chloral were given by the rectum, and if this was not sufficient, bromide was given hypodermically in a part of the body that would be the least painful if abscesses formed, as they often did after such injections. The latter were very painful, and should be given only in the stuporous stage. They usually controlled the condition. Dr. Prout then took up the pathological side of the subject. He said that the modern belief was that the epileptic storm had its seat in the cortex. Recent experimental research seemed to warrant the following conclusions: (1) That the transmission of the impulse in epilepsy was through the extra-pyramidal tracts which transmitted motor reflex impulses; (2) that the sensory portions must be irritated in order to produce the fit, and (3) the fit appeared to be a complex reflex phenomenon. The paper was founded on a study of thirteen cases. In all but two the post-mortem examination was made within seven hours after death. The changes found in the brain were by far the most pronounced in the status cases. The degree of chromatolysis seemed to depend upon the number and severity of the convulsions. In the cells of the second layer the nucleus was swollen markedly; the nuclear membrane was hazy and indistinct, and the nucleolus was frequently replaced by a granular mass. These changes were especially numerous in the status cases. Many nucleoli were found far removed from the cells

to which they belonged. He had examined the normal human brain with regard to this nucleolar extrusion, and had found it comparatively infrequent. Leucocytes clinging to degenerated nerve cells were also very frequently observed. The neuroglia was studied in seven cases, and the conditions were found to vary a good deal. A broadening of the outer cortical layer was fairly constant, and occurred apparently at the expense of the cortical layer. The condition of the neuroglia seemed to depend largely upon the condition of the epilepsy. It was more pronounced in the insane epileptic than in cases of simple epilepsy. When morbid processes attacked the nucleus the vitality of the cell itself was endangered. The increase in the neuroglia was the result of nerve-cell destruction. The authors' conclusions were: (1) it would seem that epilepsy was essentially a sensory phenomenon; (2) the essential lesion pertained to the nucleus of the cortical cell and jeopardized the cell; (3) the chromatolysis was probably a nutritional change brought about by the jeopardization of the nucleus; (4) the rôle of the leucocyte in the cortex after severe convulsions was most probably that of the phagocyte; (5) the neuroglia proliferation in epilepsy was one of the more remote sequences, and (6) epilepsy was a progressive disease of which status was the climax.

Dr. Schlapp said that he had had occasion to treat two cases of status the past summer, and both patients had recovered. One patient had had thirty attacks in eight hours. She had then become stupid and had finally developed hallucinations, the whole condition lasting two weeks. In both of the cases there was such a large quantity of albumin in the urine that the latter became solid on boiling. He thought this condition was commonly present in status. He did not think it was right to assume that the second or third layer of cells could be taken as sensory cells, so much depended upon the particular region of the brain. Most of these cells were now looked upon as associated cells, thus opposing the theory of Bruce.

Dr. Defendorf asked regarding the temperature of the patient dying of status. He had had an opportunity of studying two cases, and in both there had been what had been called "acute alteration." This was often found in other conditions, particularly when there had been high temperature.

Dr. Sachs asked whether in these cases of status epilepticus gross changes had been found that might, in some way, have been accountable for these cell changes. A number of years ago he had examined the brain of a child dying in status, and the one condition found at that time had been a very large subpial hemorrhage covering almost the entire brain. He would like to know whether in the brains examined by Dr. Prout similar conditions had been found. If they had, it did not seem to him fair to determine the true pathology of epilepsy from patients who had died in status. A truer knowledge of this pathology should be obtained from a study of the brains that had not undergone such secondary changes. The plates exhibited showed cellular changes such as had been reported in a number of very widely different diseases of the brain.

Dr. Schlapp said that he had recently seen a case presenting hemorrhages throughout all the membranes.

Dr. Leszynsky said that fifteen years or more ago he had published a paper entitled, "Epilepsy as a Cause of Death." In every one of the cases coming to autopsy there had been intense venous stasis, and in some a few small hemorrhages. One or two of these patients died within two hours, and one after a single convulsion. A very competent pathologist had made the autopsies. At that time the most successful method of treatment of these cases had been early venesection, and he had seen no reason to change his view regarding the efficacy of this treatment. The injection of chloral into the rectum was certainly very satisfactory. He had practised venesection because of the intense venous stasis, not only found at autopsy but seen in the face of the patient.

Dr. L. P. Clark said that albuminuria had been frequently observed in the cases that they had studied, yet the quantity of albumin had varied greatly, and had not been at all in proportion to the severity of the seizures. In most of their cases there had been no systematized delusions present, and the delirium had resembled that of typhoid. A very large number of gross lesions had been found as the result of the severity of the convulsions. He had seen intense venous engorgement and hemorrhages, though sometimes these had been absent in very severe cases of status.

Dr. Prout, in closing, said he did not wish to be understood as saying that the invasion of the cortex with leucocytes was characteristic of epilepsy. It was well known that such an invasion was marked in general paresis. He had only mentioned the fact as showing that the leucocyte was carrying off effete material. In speaking of the cells of the second layer he had referred to them as sensory, in contradistinction to those which we were accustomed to associate with motor phenomena. He did not think it had been conclusively shown that these cells were associational in character. Many of the sections figured in the plates showed the presence of punctate hemorrhages.

New Instruments.

A NEW VAGINAL DOUCHE.

By GEORGE H. TUTTLE, M.D.,
EAST CAMBRIDGE, MASS.

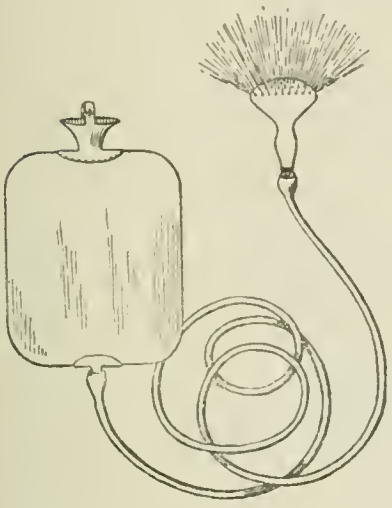
The use of hot water in the vaginal canal for the relief of congestion, inflammation, and hemorrhage, dates back far into the past. It has been proved conclusively by Dr. Murray, of Edinburgh, that the prolonged use of hot water (100° F. or more) produces a tonic contraction of the blood-vessels followed by a very slow relaxation of the same. Davenport, of Boston, states that three conditions are necessary to produce this result: the water must be fairly hot; it must be brought thoroughly in contact with the mucous membrane of the whole vagina; and the application must be a prolonged one.

To meet these requirements Professor Baker, of Boston, devised the method now in use, in which a six-quart pail and a douche pan are employed. The patient lies in bed with the hips elevated, for a period of fifteen to twenty minutes, while six quarts of water pass in and out of the vaginal canal. It is evident that in using this method the patient must lie in bed, a special apparatus must be used, a nurse is almost a necessity. Furthermore, if the hips are raised the gravity of the uterus carries it backward toward the peritoneal cavity, and, to some extent, removes its body from the effects of the hot water.

It is intended by this new device to produce the desired effects with an ordinary two-quart syringe—having a special attachment—while the patient sits at her ease on a closet seat or chamber vessel.

The mechanism and action of the new device are as follows: The douche bag is simply one of a set of syringe attachments. It is funnel-shaped, made of the finest rubber, about two and one-half inches long, and very flexible. At its fundus are a series of pin-holes, hardly distinguishable by the eye. The smaller end of the bag is stretched over the vaginal tube and held

there by winding soft string about it. The bag, being very flexible, is doubled about the hard-rubber tube for insertion. After insertion the douche bag slowly fills with water and minute streams issue from the pin-holes much as water does from a flower-pot sprinkler. The weight of the water in the bag causes it to settle until it acts as a perfect stopper of the vaginal outlet. The walls of the vagina are pressed apart by the expanding bag, and the folds and wrinkles of the mucous membrane are spread open still more by the inflowing water. This influx continues until the force of the water from the fountain bag is equalized by the various forces at work within the vagina, *i.e.*, elasticity of the rubber, contraction of the vaginal muscles, and the gravity of the water both within and without the douche bag. Thus for a time things remain nearly stationary, and the uterus, falling to the lowest possible point, is bathed in the supernatant hot water. After four or five minutes the patient pushes the hard-rubber nozzle inward—loosening the stopper—so as to let out the water which has cooled somewhat; then, by replacing the bag as before, a new accumulation takes place, and so on until two quarts of water have been used. It takes fifteen to twenty minutes to use up the full amount of water. In this way both a cleansing and a poulticing or parboiling effect is produced. At the end of the douche, the fountain bag, which has been suspended from a nail about one and one-half feet above the patient's head, is lowered to a point below the level of the vagina, whereupon the douche bag is emptied and falls out of itself.



This douche may also be used with the patient in a recumbent position, *i.e.*, in bed-ridden cases. Then a douche pan is necessary, but while taking the douche the shoulders of the patient should be raised by pillows, and not the hips as in Baker's method. In this way the weight of the uterus carries it downward as far as possible into the warm water.

I have used these bags in sixteen cases with much satisfaction to the patients and myself. These cases included leucorrhœa, abortions with hemorrhage and retained membranes, intermenstrual hemorrhages, dysmenorrhœa, and subinvolution. I have also obtained good results in cystitis and inflamed or bleeding hemorrhoids, and should expect good results in pelvic peritonitis, etc. I should think that this bag with slightly larger pin-holes might be used in the rectum when it is desired to give extra large rectal injections and have them retained.

Deaths from Consumption.—Last year in the Dominion there were three thousand more deaths from consumption than from all other infectious diseases. In Ontario one person in every one thousand of the population dies annually from consumption. Last year the province lost twenty-five hundred wage-earners from this disease, which means a direct loss of $2,500,000 and an indirect loss of an almost incalculable sum besides.—Dr. T. V. Hutchinson, *Dominion Medical Monthly*, October.

Surgical Suggestions.

The Ligature and the Value of Dry, Sterilized Catgut.—Dr. J. H. Carstens (*The Stylus*, October) makes the following points about the dry, sterilized catgut ligatures: (1) All buried ligatures ought to be absorbable. (2) All absorbable sutures must be absolutely sterile. (3) Chemicalized sutures are no more sterile than plain sutures. (4) A suture that is chemicalized is harder and remains longer in the tissues. (5) This latter is no advantage, but a disadvantage. If in a special case it is desirable that a suture should remain longer, dry sterilized kangaroo tendon can be used.

Intussusception.—Dr. A. Primrose, in the *Canadian Journal of Medicine and Surgery*, November, says that one must remember the rare possibility of spontaneous cure in intussusception. The intussusceptum may be cast off in a gangrenous condition and passed per rectum. Recently a Russian surgeon, Segal, reported a case of this character occurring in a man fifty-six years old, in whom an intussusception occurred and was cured spontaneously, the patient having passed per rectum large portions of the intussusceptum.

Hernias coexisting with adherent omentum are never safe, and especially so in men of active life and habits. In these cases it is always best to advise operation.—**In Cancer of the Breast** the presence of a large amount of fat renders less easy a thorough removal of the glands. Hence the prognosis of cure or prolonged survival must be more guarded in fat than in lean women. **In All Plastic Operations** it is important to remove the stitches as soon as possible. If left too long in the skin they will cause the formation of small scars, while if the operation has been through mucous membranes the cutting through of stitches causes the formation of little tags.—**Clubbed Fingers.** Sickly, pale children with clubbed fingers may have chronic bone disease, or bronchiectasis, or congenital heart trouble, but in the great majority of instances there is an empyema, and hence the necessity of always carefully examining the lungs in this class of children.—**Rectal Exploration.** When investigating the rectum with a long bougie it is always well to remember that there are two possible sources of error. In the first place the instrument may so double over that a mistaken idea of the length of the channel will arise. On the other hand, the bougie may be arrested by one of Houston's folds, thus simulating a stricture.—**Cancer.** It is permissible to do an incomplete operation for cancer only when it is knowingly performed with the object of relieving pain, soothing the imagination by giving the patient a faint hope, and getting rid of a loathsome sore, and because we know that recurrence in a scar is usually much less painful than the original ulcerative process.—**Pain.** In the diagnosis of malignant tumors it is well to recollect that the element of pain is quite an uncertain one. Sarcomata, for instance, are usually less painful than carcinomata, and yet we occasionally encounter cases of painless carcinomata of various regions. In some instances of adenoma the pain may be just as severe as in either of the other two. **Aneurism.** In the presence of large aneurisms of important vessels it is well to remember that operation is most likely to succeed when the occurrence is recent, when there is no evidence of aortic or mitral disease, when there is an absence of the rasp sound along the aorta, which would indicate extensive atheroma, and when there is no important visceral disease.—*International Journal of Surgery*, November.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 17, 1900:

	Cases.	Deaths.
Tuberculosis	292	147
Typhoid fever	86	17
Scarlet fever	91	1
Measles	53	3
Diphtheria	226	25
Laryngeal diphtheria (croup)	16	14
Cerebro-spinal meningitis	0	5
Varicella	12	0
Smallpox	1	0

Malaria has not received its share of attention in the etiology of acute nephritis.—J. W. Kelly.

Preservative Injection for the Embalming of Human Bodies.—

℞ Sodium arsenate	2 kgm.
Aq. bul	7,850 c.c.
Boil until complete solution, then add	
Glycerin	2,000 "
Formaldehyde	100–150 "

—Dr. A. Hewson, *Philadelphia Medical Journal*, October 27th.

Diabetic Coma.—Dr. John S. Ely (*Yale Medical Journal*, October) says: "I would warn against too precipitate withdrawal of carbohydrates from patients suffering from diabetes. In a number of cases this has been speedily followed by the development of coma, probably because of the readiness with which proteid food yields acids in the course of its decomposition. To avoid this the alkaline treatment should be instituted prior to the reduction of carbohydrates, and these should then be gradually withdrawn."

Measles.—In a study of one hundred and forty cases of measles, with reference to the appearance and value of Koplik's spots as a diagnostic signs, Dr. William J. Maroney (*Yale Medical Journal*, October) gives the following table which sums up the results of his examinations:

Time of Recognition.	Cases	Remarks.
At the beginning of the eruption.	53	In the large majority of these the children did not come under the observation of the physician until after the appearance of the eruption.
Twenty-four hours before the appearance of the eruption.	51	Slight fever, ranging from 99° to 101° F., was present in all the fifty-one cases. Slight coryza and conjunctivitis in thirty-five.
Forty eight hours before the appearance of the eruption.	20	Slight fever as above, but no coryza.
Three days before the appearance of the eruption.	4	Slight fever as above, but no coryza.
Four days before the appearance of the eruption.	2	Slight fever as above, but no coryza
Spots observed, but no eruptions.	2	Both children were very delicate. Hyperpyrexia, etc., intervened and death occurred in a few days.
No spots observed	8	In four of these the children were marantic, with very dry mouths. Two had aphthous stomatitis covering the mucous membrane.

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended November 17, 1900:

		Cases.	Deaths.
Smallpox—United States.			
Colorado, total for the State.	October 1st to 31st	75	
District of Columbia, Washington	October 28th to November 3d	1	
Iowa, Des Moines	October 1st to 31st	1	
Kansas, Wichita	November 3d to 10th	11	
Total for the State.	October 1st to 31st	27	
Kentucky, Lexington	October 28th to November 10th	4	
Louisiana, New Orleans	October 26th to November 3d	2	
Massachusetts, Taunton	October 28th to November 3d	1	
Michigan, Detroit	November 3d to 10th	1	
Minnesota, Minneapolis	October 28th to November 10th	6	
New York, New York	November 3d to 10th	1	
Ohio, Cincinnati	November 3d to 10th	14	
Utah, Salt Lake City	October 31st to November 10th	47	
Washington, Seattle	October 1st to 31st	9	
West Virginia, Wheeling	November 3d to 10th	1	
Smallpox—Foreign.			
Brazil, Rio de Janeiro	September 8th to 16th		33
Egypt, Cairo	October 7th to 14th		1
England, London	October 20th to 27th	1	
India, Calcutta	September 22d to October 13th		24
Madras	October 6th to 12th		1
Russia, Moscow	October 13th to 20th	3	
Odessa	October 22d to 27th	1	2
Scotland, Edinburgh	October 20th to 27th	1	
Glasgow	October 26th to November 2d	26	2
Yellow Fever—United States.			
Mississippi, Natchez	About October 15th	12	7

PERNICIOUS ANÆMIA AND ITS RELATION TO INHERITANCE.[1]

BY CHARLES L. DANA, M.D.,

NEW YORK.

My apology for reporting a case of pernicious anæmia is this: The history of the case shows interesting facts in the family and personal history bearing upon the question of hereditary or congenital influence in producing the disease. I have not found that this phase of the etiology or pathology has been studied; at least no reference is made to the question in the systematic treatises upon it, or in any of the recent monographs to which I have had access. The history of the case is as follows:

Joseph K——, married, aged forty-seven years, nationality German, wood-carver by occupation, was admitted to the wards of Bellevue Hospital April 6, 1900. He presented at that time the characteristic symptoms of pernicious anæmia.

Family history: The patient was the thirteenth of fourteen children, all of whom were born dead except one brother next in age to himself, and who afterward died from pneumonia. The father was a tailor by occupation, a Prussian, and was about forty years of age when his child was born. He was said to have been always a healthy man; never suffered from rheumatism or anæmia, and died at the age of seventy-seven. The patient's mother was about the same age as her husband, and died of some pulmonary disease at the age of fifty-nine. She was not a sufferer from anæmia or rheumatism, nor were there any neuroses in the family. It is evident that the mother was somewhat advanced in years when the child was born, being nearly the age of forty. Despite this history of twelve successive miscarriages there was no history of syphilis obtainable.

Personal history: At the age of ten the patient had scarlet fever and suffered at this time from inflammation of the right ear. In consequence of this illness he stated that he had to learn to talk again, and he had stuttered ever since. He gave a history of having always been healthy and able to work, never having had any acute illness, except as stated, until July, 1897. At this time he was taken with an attack which he says resembled the one for which he was admitted. This came on suddenly after a meal of hard-boiled eggs and tea. He was taken with violent pains in the stomach and was brought to the hospital. He subsequently became jaundiced, and afterward had an attack of gastro-duodenitis. He did not at this time have any shortness of breath or swelling of the feet, and he was discharged "cured." He denies ever having had syphilis.

Habits: In the past the patient had been in the habit of taking whiskey and beer in moderation. He was a hard smoker from the time he was twelve years of age until he was thirty-five, when he stopped. He began to chew at the age of sixteen, and has chewed tobacco ever since, using about three ounces a week.

He first noticed his present illness in January, 1900. At that time he found that his hands were beginning to shake at his work; they were numb; he could not pick up anything small like a ten-cent piece. Then he began to grow generally weak, but his numbness disappeared. He noticed that he would get tired during his work much sooner than formerly. He soon experienced a slight, gradually increasing shortness of breath on exertion, but paid little attention to it, and kept at his work as best he could. About the middle of February, 1900, he noticed a dizziness on getting up in the morning, which soon became so great that he would have to catch hold of something, and remain quiet with eyes shut until he could get his bearings. At this time he was unable to hold a cup of water in his hand on account of its shaking so violently. He went to the Bellevue dispensary, and was treated by several doctors there, none of whom examined his blood. He continued to get gradually worse, although his appetite was good and bowels were regular. When he lay down he had a sensation of formication in his hands and sometimes in his feet. This sensation in his hands was present only during the day. He slept well at night, and did not feel sleepy during the day. The symptoms grew worse, and so he went to the hospital April 6, 1900.

Status præsens: The patient is a short man, fairly well nourished, weighing one hundred and nineteen pounds. His complexion is the peculiar yellowish-white characteristic of severe anæmia. There is some œdema of the face and legs; the mucous membranes are pale and the sclerotics somewhat jaundiced; the tongue is smooth, pale, not coated, and moist. The heart is normal; the apex beat is in normal position; there is a soft blowing systolic murmur at the apex, not transmitted; also a booming sound in the vessels of the neck, increasing as one listens higher up. The pulse is regular, quick, full, and compressible. The arteries are thickened and tortuous. The chest is barrel-shaped: on the right side is a supernumerary nipple about three inches below the normal nipple. The lungs are hyperresonant; few bronchial râles can be heard. The liver is large, the spleen normal. There is an inguinal hernia on the left side and some œdema of the scrotum. There is no eruption on the skin. Some few enlarged lymphatic glands can be felt on the right side of the neck. The conformation of head and ears is normal. The veins of arms are prominent and nodular; not so those of the trunk or legs.

Nervous system: The epigastric, cremasteric, and plantar skin reflexes are all normal. There is no extensor toe reflex. Vasomotor reflex very sluggish, slow, and imperfect. Elbow jerk not present. Knee jerk very feeble on left; not present on right side. The legs are not hypotonic. There are a slight amount of ataxia in both hands, and a slight static ataxia. There is a little fine tremor, especially in the left hand. Muscular strength fair. Eye examination by Dr. Weeks, June 15th, showed motility of muscles and pupil normal; both discs pale. There was slight catarrhal condition of the left ear drum, the left drum head being drawn in. "Otitis media purulenta chron-

[1] Read at the meeting of the Practitioners' Society, November 2, 1900.

ica" in right ear; hearing diminished—cannot hear watch tick in right ear, watch heard at two inches in left ear; ordinary voice heard in left ear.

A later examination on April 10th shows slight ataxia of hands and slight tactile anæsthesia; dynamometer record is, right hand, seventy; left hand, sixty-five. The patient sways when standing. The knee jerks are normal. The pupils are small, the right a little larger than the left; they respond well to accommodation, and but poorly to light.

A further examination on April 19th showed slight numbness in tips of fingers and toes; dynamometer, right hand, seventy; left hand, forty; slight ataxia of left hand. Patient swayed a good deal on walking. Knee jerk diminished on right side.

The stools were well formed, of normal color, odor, and amount; without mucus or fat.

May 22d. Dynamometer record, right hand, fifty; left hand, forty; some paræsthesia and slight tactile anæsthesia of the fingers of the left hand.

The blood examinations were as follows, made by Dr. Camac, and later by Dr. Scott:

	April 9th.	April 23d.	May 14th.	June 19th.
Coagulation	Slow.			
Microcytes	Numerous.	Numerous.	Numerous.	
Macrocytes	Numerous.	Numerous.	Numerous.	
Poikilocytes	Numerous.	Numerous.	Numerous.	
Degeneration areas	Numerous.			
Red blood cells	1,400,000	1,800,000	1,008,000	958,000
White blood cells	6,000	7,000	7,000	4,400
Hæmoglobin	25 per cent.		25 per cent.	23 per cent.
Stained specimen — Red blood cells.				
Polychromatiphilia	Marked.	Marked.	Marked.	
Normoblasts	1.	2.	4.	
Gigantoblasts	2.	6.	7.	
White blood cells.				
Small mononuclear	35 per cent.			
Large and transitional	25 per cent.			
Polynuclear	40 per cent.			
Eosinophiles	0			

The patient's mind was clear, but he was somewhat apathetic. He complained of no headache or pain of any kind. He was quite weak and easily got out of breath. He slept well at night; his appetite was good; his kidneys acted freely, and he had an average of about two stools a day, which were normal in appearance. The general course of the disease during the next three months corresponded very perfectly with Addison's classical description and hardly needs a recital here. There was a slow but steady progress downward. Puffiness of the face, weakness, breathlessness on slight exertion, characteristic pale-yellowish look, swelling, all became very marked. The patient was quiet but not despondent or complaining. He continued to suffer from the paræsthesia and clumsiness of the fingers. The blood examination, as shown in the table, revealed the characteristics of pernicious anæmia. It was not affected by any form of treatment. High rectal injections, arsenic, iron, bone marrow, purgatives, and tonic measures of all kinds were used without avail. During the progress of the disease the urine was measured daily. It ranged in amount from forty-five to sixty ounces, and became a little less as the weather grew warmer.

Urinary examination: April 7th. Specific gravity, 1.032; acid; no albumin or sugar microscopically; phosphates and urates; total amount for the day sixty-two ounces.

May 19th. Color, light straw; specific gravity, 1.013; alkaline; urea sixty-five per cent.; no albumin or sugar; microscopically negative; total amount, fifty-eight ounces.

June 18th. Color, amber; specific gravity, 1.013; no albumin or sugar microscopically; urea, .769; few hyaline and granular casts; epithelial cells, phosphate, and urates; total amount, forty ounces.

These records show a gradual diminution in amount, a deficiency in urea, and low specific gravity, and deficient total solids. They contrast with the rather free elimination from the intestines.

The stools showed nothing abnormal; no parasites were seen after purging. There were two to three stools daily up to the time of his death. The digestion was good. There were no symptoms pointing to the disturbance of the gastro-intestinal tract, beyond the free action of the bowels. The temperature during the first month averaged about 100° F., ranging from 99.5° to 100.5° or 101° F.; there was a daily rise in the afternoon of about a degree. In the next two months it ranged about one-half a degree lower, keeping slightly above normal until the terminal rise at the time of his death. This slight febrile rise is characteristic of typical cases of pernicious anæmia.

The pulse beat was about 100, ranging from 95 to 105.

Respiration slightly accelerated, averaging 24 in the last month of life, running often to 28.

There was no further development of the nervous symptoms, which indicated a slight involvement of the posterior columns in the cervical region of the spinal cord, that being the part of the spinal cord most often affected in this disorder.

The patient steadily grew weaker, more œdematous, and more anæmic. He died of exhaustion on June 15th.

I do not intend to discuss the question whether pernicious anæmia is a specific type of disease. It seems to be very well settled that there is such a disease which has clinical characters that make it separate and recognizable, when the clinical history and blood examinations are studied together. I believe the exciting causes of the disease are many and various. It is my purpose to-night to show that the victims of it all possess one common thing, viz., a teratological defect or weakness in the blood-making organs.

In the study of nervous diseases one becomes impressed with a fact which does not seem to have been appreciated by pathologists in their studies of pernicious anæmia—this is the occasional unequal vitality of the different tissues of the body. For example, in the muscular dystrophies we know that the muscular system is congenitally short-lived and wastes away before the individual's other organs are even matured. In hereditary chorea the gray matter of the brain cortex, especially in the central convolutions, dies before the man is forty. In certain forms of primary dementia the same fact is true. In locomotor ataxia and the spinal atrophies and other degenerative diseases, certain systems are born with a weak vitality and succumb to infections, toxins, or accidental injuries, which do not affect the other parts. Of the millions who get syphilis only some thousands have tabes, and of the thousands who are poisoned with lead only a few have an atrophy of the cornual cells. The same law, I believe, applies to other structures. The kidneys and the liver atrophy and die early in some, while others subjected to the same influence continue healthy. These tissues have inherited a feeble resistance to deleterious agents.

The factor of teratology or unequal vital endowment of the tissues is one of the most important and compelling in the explanation of progressive degenerative diseases of the human body.

There are certain microbic poisons and toxins so potent that they can sap the vitality of even the soundest tissue; but such potently malignant agents cannot be always invoked by the pathologist. Are they sufficient to explain pernicious anæmia?

The theory of atrophy of the gastric tubules is admitted inadequate, and has been abandoned. Only a small proportion of the victims of intestinal parasites have pernicious anæmia. Among twenty-three African

negroes all were found to have intestinal parasites and twenty-six had ankylostoma, but none showed any signs of anæmia.[1]

The theory of a specific infection is still only a guess. The theory of an auto-intoxication from the gastro-intestinal tract is the one which now holds the most support. It is based upon the evidence of gastric disease, of intestinal parasites, and of the discovery of certain ptomains in the urine. Dr. W. Hunter has found putrescin and cadaverin, substances caused only by micro-organisms, in one case; but these substances are also found in cysts. Micro-organisms and parasites have often been discovered in the bowels, but I cannot find any very positive or convincing evidence of an adequate auto-toxæmia, and no therapeutic attempts addressed to this condition avail at all. It is difficult to understand how so powerful a hæmolytic agent could be present there and not cause more marked general symptoms. It is a characteristic of all progressive degenerations that remedies never permanently avail. We may, however, suppose, if you wish, that there is some auto-poisoning. It would not be sufficient, according to my point of view, if there were not an inherent lack of vitality in the blood cells also. In the same way the posterior spinal roots, or anterior horn cells, would not atrophy and die if, superimposed upon their natural weakness, there were not some luetic or lead poison to affect them. The muscular dystrophies often start in after an acute infectious disease.

All the degenerative diseases are apparently diseases of lysis, not of genesis. The full-grown cell is attacked, not the embryonal cells. So in pernicious anæmia it is now generally agreed that it is not the blood-making organs but the finished blood which is attacked. It may be objected that the blood is not a tissue like muscle or nerve or liver, but a tissue feeder. Still the analogies are sufficiently perfect. The red blood cell is a fully developed anatomical unit with a definite life history which must run a certain course, in order that it may perform its functions. If it dies too soon through lack of original endowment of vitality, the process is the same as that of the degenerating muscle or nerve or kidney cell, which lives but forty years instead of seventy. The argument, to be sure, would make the original defect lie in the blood-making organ. This is not able to turn out a cell that can live its proper life, though it may mature and become for a time a healthy cell. I should accept this point of view and make pernicious anæmia a disease in which, owing to bad endowment, those organs begin to fail in their work after a certain number of years. This does not affect the practical, accepted fact that the anæmia is due to the killing or dying off of cells which start out apparently in proper number and appearance.

It might be asked, "Why should we not have pernicious anæmia in old age if this doctrine is true, since in advanced life other tissues grow old?" As a matter of fact, there is the same general atrophy of the blood at that period, but nature has arranged it that fatal degenerative diseases occur mostly before or at middle life. It seems that after that point is safely passed it means that the individual has received usually a well-balanced endowment and that the machine will run on with a fair degree of certainty, so far as degeneration is concerned. After this period it is mainly secondary to the arterial sclerosis and defective vascular supply.

In my own case the history of the family is most striking, and shows an extraordinary lack of vitality on the part of the generation to which the patient belonged. Out of fourteen children twelve died in infancy, and the other two before the age of forty. There was no evidence of lues, and though this may have been present, it is rare for this trouble to cause more than three or four miscarriages or early deaths.

I have not been able to look up the personal histories of the many cases of pernicious anæmia reported, but in the systematic articles on this subject by Stengel, Cabot, Henry, Howard, Shattuck, Coupland, Pepper, Ehrlich, and Lazarus, and in the recent numerous discussions on this topic, I find no notice of any careful study of the family history. Such studies are always difficult and usually negative, but a few very positive cases like my own ought to carry weight.

In cases in which a mother gives birth to a long series of still-born children it has been found that some of those who finally survive have teratological defects. Thus Ballantyne[1] reports the case of healthy parents who had eight children, the first two were normal, then came an abortion, then four pregnancies resulting in still births, or nearly such with hydrocephaly, anencephaly, spina bifida, malformed feet, malformed hands, absence of radius, then a normal child.

I hope that this attempt at an oblique illumination may at least start some inquiry in a new direction, even if it only leads to the conclusion that my case was an accident or a coincidence. I shall not easily believe this so, because the view which makes pernicious anæmia a teratological defect has so much in analogy to support it.

GASTROPTOSIS.[2]

By GEORGE ROE LOCKWOOD, M.D.,

NEW YORK.

The descriptions in the books of the symptoms of gastroptosis are hopelessly obscure and chaotic, but not more so, unfortunately, than is the complexity of symptoms actually presented by the patient. When one goes over the series of his cases in analytical study, it becomes painfully evident that no two are alike, and that characteristic and diagnostic points are few and misleading. It seems to me that the present jumble arises from the fact that we are apt to consider gastroptosis a morbid entity, and that we do not go closely enough into the other conditions which may be found in the displaced stomach—atony, gastritis, and disorders of secretion and sensation, for example—any of which or all of which may be potent factors in the symptom complex.

Let us take the heart by analogy—a hollow muscular viscus to which the stomach may well be compared. A diagnosis alone of mitral insufficiency or of enlargement is hardly up to date. The cardiac musculature, the probabilities of present or future degenerations, the general recuperative power of the patient, the condition of the arteries—all these and more have to be taken into consideration. In like manner, with the stomach, factors other than the mechanical displacement should enter into the study of the case.

The cases upon which the facts of the paper are based are taken from private practice, and have all been under observation a long enough period of time to allow of their being carefully studied. The cases of hospital patients who return to unhygienic living and erratic diet have been totally excluded as have been all of those cases which have been seen, diagnosed, and have passed from under observation. Such a selection seems to me the fairest, and the one that promises to give the most accurate data.

It may here be said that the facts obtained coincide with the writer's experience of other cases, greater in

[1] American Journal of Obstetrics, 1900, p. 577.

[2] Read before the Clinical Society, May 25, 1900.

number, seen in public practice, of which records are incomplete.

The cases thus selected, the majority of which have been under constant observation for a number of months, number 45, 8 males and 37 females. Of the 45 cases

3	patients	were	between	20	and	25	years old.
9	"	"	"	25	"	30	" "
5	"	"	"	30	"	35	" "
6	"	"	"	35	"	40	" "
10	"	"	"	40	"	45	" "
6	"	"	"	45	"	50	" "
3	"	"	"	50	"	55	" "
1	patient	was	"	55	"	60	" "
0	"	"	"	60	"	65	" "
2	patients	were	"	65	"	70	" "

The marked preponderance in adults during the most active portion of life, the storm and stress period, is here well illustrated—36 cases occurring between twenty-five and fifty years of age, 9 cases at other times. Cases in persons under twenty, giving symptoms, have not been seen, quite contrary to Meinert's experience. A cause adequate to explain the gastroptosis was found in but a single case. This patient was a man forty-five years of age, who three months after marriage developed the symptoms of incomplete intestinal obstruction. Exploratory laparotomy by Dr. B. F. Curtis showed the intestines in a contracted condition, resembling the appearance of spastic ileus. The gastro-hepatic omentum was so lax that the stomach could easily be pulled about the abdominal cavity. The organ was of normal size and muscular tone. The mesocolon was also long and lax, allowing of an extreme degree of coloptosis.

There have never been gastric symptoms either before or after the operation. Tight lacing did not appear to be a cause in any of the cases. Rapid emaciation was not found in any of the cases. Laxity of the abdominal wall was not a marked feature. Of the 37 women 25 were nulliparæ, 3 had one child, 5 had two children (in one, diastasis), 1 had three children, 1 had four children (diastasis), 2 had children, number was not stated (in both, diastasis; one was sixty-seven years old, one seventy-two years old).

Only four cases of diastasis recti were encountered: one in a IIpara, one in a IVpara, two in old people, multiparæ.

An appreciable displacement of the right kidney was present in about one-half the cases.

It did not seem to me that any woman of the series laced more than normally, and that the corset was responsible for a single case. This is contrary to the experience of Fleiner and Meinert.

Only one case showed chlorosis. I have examined a large number of chlorotic girls, and can dispute the statement of Meinert, that gastroptosis exists in every chlorotic girl. Meinert bases his experience on one hundred cases of chlorosis. It probably depends on what dividing line you draw between a normal and a displaced stomach, for Meinert says fifty per cent. of girls twelve years old have gastroptosis, eighty per cent. of girls fourteen years old have gastroptosis, ninety per cent. of adult females have gastroptosis. These statistics are entirely at variance with our experience in this city.

Stiller's sign or stigma of neurasthenia—the mobility of the tenth rib—was not always looked for, but when search was made the rib did not seem unattached.

My general impression is that gastroptosis is far more common among the upper classes—a more frequent disease of private practice than of hospitals. Whether this is due to the more highly sensitive nervous systems of the upper classes, or to more systematic use of the corset, or is due to the fact that hospital and dispensary patients are not carefully examined, I do not know. The last-mentioned reason seems to me the most explanatory.

An exciting cause for the manifestation of symptoms occurred very strikingly in twenty-four of the forty-five cases, and is stated as follows:

1. Well till six years ago. Then the only sister died after a long illness.

3. Well till six years ago. Then nervous prostration developed from "adequate cause" (love affair). Since then the patient never was well.

5. Never well since domestic complications, six years ago.

6. Well until she lost her money, and had to keep a boarding-house; at about the same time she developed exophthalmic goitre.

8. Well till two years ago. Then she had a stillborn child; nephritis and fever followed.

10. Constantly ill for four years, directly following a fall through the ice.

16. Well till husband had pneumonia four years ago.

17. Lost money two years ago, and has had to teach music.

19. Well till six years ago. Then, under domestic strain, she developed hystero-epilepsy.

20. Lost money six years ago. Since then constantly stomach sick.

21. Constantly ill since death of only sister, eight years ago.

22. Severe attack of gall stones eight years ago. Never well since.

23. Six months' growth of ovarian tumor.

24. Well till runaway accident six years ago, in which she was thrown from carriage. Constant indigestion since.

26. Husband died eight years ago.

27. Husband died three years ago.

28. Two and one-half years ago operation for cervix and curetting.

29. Well till one year ago. Then severe overwork and poor treatment (insufficient diet).

30. Three to four years following prolonged nursing of a sick patient.

31. Woman, aged seventy-two years, with lax abdominal walls; was well till her husband died two years ago. Since then constantly ill.

34. Well till one year ago, when she had exhausting hemorrhage, said by Trudeau to be "vicarious menstruation." This came at the same time as severe domestic unhappiness. Never well since.

36. Well till two years ago. Patient had had exudative nephritis for six years, but the stomach was perfectly satisfactory. Then the father became ill, the home was given up for residence south. Since then, nervous worry and stomach symptoms.

40. Well till one year ago. Then she developed chlorosis, and her stomach began to trouble her.

Of these 24 patients 23 were women, 1 was a man. Probably the man would have done differently if at the time he had received rational treatment.

Of all the complications of gastroptosis atony is the most important, and is usually the exciting cause of symptoms. In the pre-atonic period the symptoms seem to be intermittent, induced by fatigue or by emotional or nervous strain, and are interrupted by more or less lengthy periods of well-being. These intermittent symptoms seem almost entirely due to gastric neuroses, either sensory or secretory. When, however, atony develops, the clinical picture changes. The patients no longer feel well after the summer's outing, but there is more or less continual gastric distress. Flatulence, loss of appetite, or an appetite that is too easily appeased, and an increasing malnutrition, together with any or all of the multiple forms of neurasthenia, are the most prominent symptoms.

Of the 45 cases, atony was absent in 19, slight in 6, moderate in 16, marked in 13. In one of the cases there was hypermotility.

I. Cases without atony. In the ten cases (four males, six females) there were practically no symptoms. It will be noticed that as atony increases there is an increased number of neurasthenic females. In thirteen cases no gastric analysis was made because no stomach symptoms were present. One case showed hypermotility, so that the stomach was continually empty one-half hour after the test breakfast. Aside from a feeling of "goneness" coming on two hours after eating and lasting until the next meal, no gastric symptoms were present. In two cases gastric analysis showed normal acidity and digestive power. In one of these there was coloptosis and obstinate constipation, with loss of appetite. The other case was a nervous society woman, who complained of a peculiar feeling in the pit of her stomach after eating whenever she was overtired. One patient showed in the fasting condition considerable amount of mucus—the test breakfast showed low acidity (16) without HCl. The symptoms were weakness, insomnia, and flatulence, and entirely disappeared after one month's treatment by lavage and Kissingen water. Here the symptoms were due, not to atony or gastroptosis, but to an intercurrent gastritis.

In one case moderate gastritis was present (total acidity 40, mucus in fasting stomach; in test breakfast thirty small pieces of gastric mucosa were found), but the symptoms were entirely neurotic, and consisted in peculiar feelings during the height of gastric digestion. A full diet, with small doses of bromide, chloral, and chlorofom water, brought about entire cessation of symptoms in two days. The superficial erosions gave no symptoms.

One case (an epileptic) presented the complication of periodic vomiting of gastric juice ("gastroxynsis of Rossbach") together with gastric and cutaneous hyperæsthesia, resembling the gastric crises of locomotor ataxia. Between attacks there was steady hyperacidity (nearly 4 per cent.). No result was obtained by treatment.

One case showed hyperacidity (.025 per cent.) with superficial erosions. Sections of the mucous membrane in the wash water presented the lesions of mucous gastritis, and a small amount of interstitial infiltration.

There is nothing very definite about the symptomatology of this class without atony: 1 case of hypermotility; 1 of moderate gastritis and gastric neurosis and superficial erosions; 1 of marked mucous gastritis; 5 giving no symptoms; 1 of superficial erosions and hyperacidity; 1 of gastroxynsis. hyperacidity, epilepsy.

Of the ten cases six might well be described as neurasthenic.

II. Cases with slight atony, six cases. Of the six cases·

1. Complicated by hyperacidity: principal symptoms, gas on empty stomach and heartburn. The patient showed gastric hyperæsthesia from acids described by Talma. Symptoms steady for ten years. The patient was treated by atony diet and alkalies and small doses of chloral; he recovered. He has been well for two years past.

2. Girl, aged twenty years, was well till she developed chlorosis two years ago. Then she had attacks of gastroxynsis. Hæmoglobin twenty-seven per cent. Treated by iron and recovered entirely.

3. Male, neurasthenic. Gas at 6 A.M. always, for past three or four years. He was much improved by atony diet, and for past year has had no complaint.

4. Female, aged twenty-eight years. Nausea, constipation, weakness, and anæmia. Examination of gastric contents showed mucus in fasting stomach and subacidity. By lavage and Kissingen and intragastric faradism she made good recovery. This case was interesting because of quick response of motor functions to intragastric faradism, and because after any fatigue or mental excitement atony returned as a temporary condition.

5. Female, aged thirty years. She was well until some nervous strain occurred, then lost appetite and had gas constantly. Chemical analysis showed slight mucous gastritis, normal acidity. Treatment by Wiesbaden, with marked improvement. Still under observation.

6. Female, aged twenty-eight years. She had attacks of pyloric spasm for two years at intervals, with nausea, flatulence, and loss of flesh and strength; slight atony, pulsating and tender aorta, cutaneous hyperæsthesia. Mucus in fasting stomach. The test breakfast showed anacidity. Treatment by lavage, Kissingen, hot wet flannels. Still under observation.

Synopsis: 1. Hyperacidity; recovered. 2. Gastroxynsis, chlorosis; recovered. 3. Hyperæsthesia and neurosis; recovered. 4. Chronic gastritis; recovered. 5. Gastritis; improving. 6. Gastritis anacida: improving. Three of the six might be considered neurasthenic.

III. Cases with moderate atony; fourteen cases, all females.

In all of these cases there were slight, constant symptoms—loss of appetite, vague feeling of distress after eating, and eructations of gas. In all there were periods of exacerbation of symptoms regularly induced by fatigue or nervous strains.

In six cases no gastric analysis was made, as there did not seem to be sufficient severity of symptoms, and the six cases were all in nervous women of marked neurasthenic habit. In one of the cases there was "peristaltic unrest."

Of the eight cases with gastric analysis, one showed normal acidity after test breakfast. The fasting stomach contained regularly 20–40 c.c. of glairy mucus reacting to free HCl., but no food remains even after the Riegel dinner taken seven hours previous to the examination. The symptoms were loss of appetite, gas, pyloric spasm, gastralgia, oliguria, neurasthenia, and insomnia.

Two cases showed normal acidity and absence of mucus. The symptoms of one were weakness and anæmia which disappeared under treatment. The other case showed anæmia and oliguria which were relieved by iron, diet, and diuretics. The fourth and fifth cases showed gastritis subacida. The sixth and seventh cases showed hyperacidity and gave the symptoms of hyperacidity only. The eighth case showed mucous gastritis with normal relation of acidity—neurotic vomiting and gastralgia—rapidly relieved by lavage and internal administration of bromides. There were only two patients in forty-five who vomited, and in these cases the vomiting was distinctly a neurosis.

To recapitulate this group. Six cases gave scarcely any symptoms of any severity—all were neurasthenic, and did well without local gastric treatment. Eight cases were analyzed: Four cases had normal acidity, two cases had subacidity, two cases had hyperacidity. Thirteen of the fourteen were neurasthenic—all females.

IV. Cases with marked atony. This group comprises fifteen patients, including two males, and constituted the worst set of cases. They all presented constant gastric symptoms, were never free from indigestion, and were all more or less incapacitated, thirteen being practically semi-invalids. Gastric analysis was made in all but one case. In all of the fourteen cases examined mucus was found in the test breakfast, and in eleven cases was found in the fasting stomach.

Eight cases showed hyperacidity, three cases showed normal acidity, three cases showed subacidity. One of the last three gave practically no HCl, either free or combined.

All the fifteen cases were neurasthenic, and all to a fairly intense degree.

1. Female, aged twenty-nine years; flatulence, heartburn, pyloric spasms, hysteria, insomnia, oliguria, indicanuria with constipation, weakness; semi-invalid six years. Gastroptosis, atony, periodic slight dilatation, coloptosis, mucous colitis. Slight mucous gastritis with hyperacidity.

2. Female, aged forty-eight years; flatulence, neurasthenia, semi-invalid. Hyperacidity, moderate gastritis.

3. Female, aged thirty-five years; gas, fluctuating acidity (from 6 to 144), bulimia, profound neurasthenia, peculiar head symptoms with visual aura resembling petit mal, gastroptosis, atony, enteroptosis, intestinal auto-intoxications; invalidism.

4. Female, aged thirty-five years; gas, distress in epigastrium, feeling of load. Alternating diarrhœa and constipation. No colitis. In wretched health continually. Hyperacidity. No mucus.

5. Female, aged sixty-seven years; constipation, gas and flatus, acidity, semi-invalid. Gastroptosis, atony, hyperacidity, slight colitis, diastasis recti.

6. Female, aged forty-two years; pain, neurasthenia, emaciation, slight mucous gastritis and subacidity. Has phthisis, exophthalmic goitre, and hay fever.

7. Male, aged forty-six years; gas, anorexia, attacks of pyloric spasm, retention followed by congestive headache. Never has a well day.

8. Female, aged fifty years; for ten years nausea and vomiting, pain, gas, alternating diarrhœa and constipation. Analysis: normal acidity. No mucus. Patient more or less of a wreck, weighing less than one hundred pounds.

9. Female, aged twenty-nine years; for fifteen years an invalid. Gas, neurasthenia, oliguria, weakness. Mucous gastritis with subacidity, marked atony.

10. Female, aged twenty-six years; for four years pains, gas, nausea, vomiting, insufficient diet, constipation. Weight seventy-one pounds in travelling-dress; five feet six inches tall. Gastroptosis, atony, hyperacidity, neurosis. Invalid.

11. Male, aged forty-eight years; for ten to twelve years never well. Gas, insomnia, loss of flesh and strength. Normal acidity, no mucus.

12. Female, aged forty-two years; for ten years gas, sore feeling, pyloric spasm, neurasthenia. Slight mucous gastritis. Normal acidity. Invalid.

13. Female, aged forty-eight years; for six months pain, gas, acidity. Lost twenty-five pounds in six months. Analysis shows hyperacidity. Stomach displaced and apparently adherent to ovarian cyst.

14. Female, aged twenty-six years; for one year constant peristaltic unrest, flatulence. Analysis shows slight gastritis; fasting stomach empty. Test breakfast shows high acidity. Superficial erosions.

15. Female, aged thirty-six years; for two years severe and constant flatulence, loss of appetite, emaciation, and loss of strength. H. forty-two per cent. Fasting: small amount of mucus of alkaline reaction. Test breakfast f. a. 16. No free acid, no lactic.

It becomes very evident on reviewing these groups of patients that the severity of symptoms and the obstinacy of their course depend to a great extent upon the degree of the associated atony, and, moreover, it would seem as if atony progressed with advancing neurasthenia and malnutrition in equal strides. Of the cases showing moderate or marked atony, not one well-nourished non-neurasthenic victim can be found. Paul Cohnheim, Boas' able assistant, in reviewing a series of cases seen in Boas' clinic, says in a recent number of the *Archiv für Verdauungskrankheiten*: "Gastric atony is a constitutional malady—a part only of a general muscle and nerve weakness. It is never cured by bland diet, but only by raising the general nutrition, and by increasing the strength of nerve and muscle. The symptom complex which we call atony, is never found in well-nourished patients."

These expressions of Cohnheim's coincide completely with my own experience in these cases, and I place especial emphasis upon this point when we consider the treatment of the condition. Left to themselves, these patients assume a starvation diet by which the real difficulty is increased. Fatten them, nourish them, test the motor and chemical functions of the stomach by test meals, and so prescribe a suitable diet, and then and then only is no class of cases so encouraging or gives better results.

Continual secretion of gastric juice (Reichmann's symptom). Continual secretion of gastric juice was not found in any of the cases. Six patients showed mucus in fasting stomach without traces of HCl. All these six had gastritis. In four patients mucus and free HCl could be demonstrated in the fasting condition.

To constitute a true continual secretion, it is generally agreed that the presence of HCl must (1) be constantly found in the fasting stomach mornings after a lavage the previous night; (2) that the quantity should be fairly considerable. Of course, an arbitrary line must be drawn for the exact quantity required to justify a diagnosis. This quantity Boas places at 100 c.c., Riegel at 50 c.c. Smaller quantities may be present from time to time, as an artefact, and are to be disregarded. In no one of the four cases mentioned did the quantity exceed 25 c.c. It is, moreover, interesting that all of these cases were cases complicated by atony; two of the four cases were further complicated by superficial erosions.

Acidity. The relations of acidity to gastroptosis are very interesting, especially when considered in connection with complicating atony and gastritis.

It was found impossible to draw fine distinctions between various grades of acidity, because the acidities varied so much on various days. It may be stated (1) that a displaced stomach is a neurotic stomach; and (2) that the majority of gastroptosis patients requiring treatment are neurasthenics. These two conditions, the local and the general, evidently furnish reason enough for marked fluctuations in the secretory functions of the stomach. Just here I would add that to determine the actual fluctuating power of any stomach one single examination will not suffice, but that examinations should be made at stated intervals and under varied conditions. A stomach, for example, that will digest perfectly the Boas meal of bread and water, may fail utterly to do its work when confronted by the Riegel dinner of a plate of beef soup, 150–200 gm. of beefsteak, 50 gm. of potato purée, and one roll.

In the thirty-three cases examined, however, acidities, while fluctuating, kept within certain broad limitations, with the exception of one case (gastroptosis, atony, post-operative hysteria) in which acidities varied between 6 (.07 per cent.) and 144 (.5256 per cent.) without apparent reason.

The easiest and most practical classification seems to be: (*a*) normal acidity, 40–60 (.146 per cent. to .219 per cent.); (*b*) hyperacidity, 60 and over; (*c*) subacidity, 40 and under.

Of 33 cases examined there were, (*a*) of normal acidity, 10 cases; (*b*) of hyperacidity, 15 cases; (*c*) of subacidity, 8 cases. Cases with lower acidity than 22 (.08 per cent.) were not encountered.

Thus it will be seen that the great majority of gastroptosis cases show ample acidity to digest ordinary

food, and that if symptoms are present they must be referred, for the greater part at least, to derangements of motor or secretory functions. Reference will be again made to this point in discussing the treatment of these cases.

Again, the mildest cases are generally to be found in the subnormal group; the severest cases, *i.e.*, those presenting the greatest severity of symptoms, are about equally distributed among the normal and hyperacid cases.

Let us glance for a moment at the relation between acidity and atony for an explanation:

Relation of acidity to atony. (1) Of cases with normal acidity (10), 1 case showed no atony, 0 case showed slight atony, 3 cases showed moderate atony, 6 cases showed marked atony.

Summary: One case showed atony absent or slight; 9 cases, atony moderate or marked.

(2) Of cases with hyperacidity (15), 3 cases showed no atony (one, epilepsy and gastroptosis; two, erosions); 2 cases showed slight atony; 5 cases showed moderate atony; 5 cases showed marked atony.

Summary: 15 cases; 5 cases atony absent or slight, 10 cases atony moderate or marked.

(3) Of cases with subacidity (8), 2 showed no atony, 2 showed slight atony, 1 showed moderate atony, 3 showed marked atony.

Summary: 4 cases showed atony slight or absent, 4 cases showed atony moderate or marked. The large proportion of atony present in cases with normal or hyperacid conditions seems, therefore, to afford the connecting link between the acidity and severity of symptoms.

Acidity and gastritis. By going over this list of acidities and by marking off those patients with gastritis, the following data are furnished:

(1) Cases with normal acidity (10), 1 case had gastritis, 9 cases had no gastritis; gastritis, 10 per cent.

(2) Cases with hyperacidity (15), 5 had gastritis, 10 had no gastritis; gastritis in 33 per cent.

(3) Cases with subacidity (8), 5 had gastritis, 3 had no gastritis. (The latter three were very profound neurasthenics. In one case after a four-weeks' rest cure the acidity had passed into the hyperacidity class.) Gastritis, 62 per cent.

These figures show the effect of a mucous gastritis in re lucing acidity. Such facts would seem to show:

1. That cases of gastroptosis uncomplicated by gastritis give, as a rule, normal or excessive acidity.

2. That gastritis, when it does occur, brings down the acidity somewhat to normal or subnormal; but it is rare, in gastroptosis and gastritis combined, to meet with the low acidities encountered in gastritis alone.

3. Owing to the fairly high acidities seen in these complicating gastritides, the ordinary symptoms of gastritis are not marked.

In no case of the series did the gastritis seem a factor in the severity of the case. A few of the cases were treated by lavage and by mineral waters, and in every case mucus practically disappeared, subacidities became higher, and the patients did well.

An analysis of pain is somewhat interesting. Pain was complained of by 15 of 45 patients. In 6 the pain was evidently due to pyloric spasm. All had marked atony, with normal or increased acidity in equal proportions (3 of each). In no case was dilatation present, except in two cases as a transitory phenomenon after extreme degree of spasm. In 4 patients pain was due to superficial ulcerations. All of these were hyperacid cases; three had gastritis.

Two patients presenting superficial erosions gave no pain; one was subacid, one hyperacid. It is somewhat striking that 6 of the 45 cases should be complicated by superficial erosions, especially as the 6 cases are all of different types and present very little in common, except the large proportion of hyperacidity (5 of the 6).

In 2 patients the pain was evidently due to dragging on the gastric ligaments, and disappeared after the use of an abdominal belt. In 2 patients the pains were evidently of a neurotic nature, in 2 cases they were due to hyperacidity.

The relations between atony, gastroptosis, and dilatation of the stomach are of paramount interest, especially as the whole subject stands at present on debatable grounds.

A great deal of trouble may, however, be averted, if we clearly understand what is meant by the term "dilatation." It cannot be affirmed with too much emphasis that the actual size of the stomach has nothing to do with the condition that we call dilatation; hence the term is a misnomer, and should pass from our medical nomenclature and be replaced by the term "muscular insufficiency."

It is entirely in this significance that I use the term dilatation in this paper, meaning not the size of the stomach, but its power to expel its contents through the pylorus into the intestine. If a patient is given at night two roll sandwiches and water, and if on the following morning food-remains are found, there is present muscular insufficiency, ectasia, or dilatation (whichever term we prefer). This muscular incapacity is the main fact—the exact size of the insufficient stomach is entirely a secondary and insignificant affair. Understanding, then, exactly what is meant by the term, it is evident that dilatation theoretically can arise only (1) when the muscle is too weak to expel stomach contents through a normal pylorus or (2) when obstruction exists at the orifice. While acute muscle weakness has been known frequently enough to lead to acute dilatation, there is no evidence that chronic primary muscle weakness alone has ever led to the chronic dilatation. Cohnheim, in Boas' clinic, after an experience of many hundred cases of pure atony, has never seen ectasia follow, and while he and Boas are not prepared to deny that such may result, they would regard dilatation from such a cause as extremely rare. In this view Boas is supported by a brilliant minority, Schreiber, Ullmann, and Kausch. Kausch, writing from Mikulicz's clinic, has never observed a case of pure atony ectasia. On the other hand stand in array Riegel, Ewald, and Rosenheim. The high position of the belligerent parties adds an additional zest to the combat. There can be, however, no doubt that gastroptosis may be followed by dilatation, and that the dilatation may come about in one of three ways: (1) kinking of the duodenum; (2) pyloric spasm; (3) arterio-mesenteric constriction.

1. Kinking of the duodenum usually occurs at the junction of the superior horizontal and descending portion of the duodenum. If the stomach wall is of fairly good strength, compensatory over-activity may occur just as the left ventricle undergoes compensatory hypertrophy in aortic stenosis. It may be only when the stenosis increases, or when the vital powers fail, that muscular insufficiency of the stomach results.

2. Pyloric spasm may result in one or more of three ways: (*a*) hyperæsthesia of the pars pylorica or pyloric antrum; (*b*) hyperacidity; (*c*) reflexly from gaseous accumulations.

Pyloric spasm is extremely apt to occur in gastroptosis with atony, as in these cases all three predisposing causes are apt to be combined. Transitory spasms may be followed by transitory muscular insufficiency, as in the following case:

Male, aged forty-five years, markedly neurasthenic; gastroptosis, atony, hyperacidity; generally increased reflexes; occasional attacks of spasm, nausea, vomiting of rancid acid material, congestive headache followed by diarrhœa. During one of these attacks the fasting

stomach contained 200 c.c. fluid of rancid odor, with food remains. Total acidity, 56; free HCl, 36; combined HCl, 4; total HCl, 40; salts, 6; organic acids, 10 (no lactic, chiefly butyric).

Subsequent examinations have shown the stomach perfectly empty in the fasting condition. Under treatment no further attacks have been noted for three years.

It is more than probable that many cases of continual or periodic secretion of gastric juice are to be explained on this theory. It is important to recognize and prevent pyloric spasms in order to conserve the motor function of the stomach.

A rarer cause for dilatation has been described by Arnold Albrecht in a recent number of Virchow's *Archiv*. The course of the superior mesenteric artery is such that whenever downward traction is made on the intestinal mass, the root of the mesentery with the superior mesenteric artery and veins exerts direct pressure on the junction of the duodenum and jejunum. A passage obstruction may be thus caused that may run even an acutely fatal course, as penalty, from some unknown cause, after surgical operations. It has seemed to me, in experiments on the cadaver, that the downward traction of enteroptosis may be sufficient to cause considerable insufficiency in an atonic stomach.

My own conviction is that atony alone does not cause dilatation, but that one of these three mentioned causes will be found present if food remains are detected in a fasting stomach. Although the atonic stomachs are often larger than normal, they are, with rare exceptions, empty of food remains in the fasting condition, and I would be inclined to regard any muscular insufficiency as due to a passage obstruction, kinking, pyloric spasm, arterio-mesenteric constriction, or the contraction of cicatrix or neoplasm.

Treatment: Enough has been said to emphasize the point that gastroptosis is not a morbid entity, but that it merely predisposes toward other conditions that require treatment. In general words, these propositions of treatment may be made:

1. The displaced stomach is a neurotic stomach, and subject to a variety of sensory, motor, and secretory neuroses (pains, spasms, hyperacidity).

2. In the great majority of cases, the gastric juice shows normal or increased digestive power.

3. That atony and neurasthenia progress hand-in-hand, and either one cannot be treated alone.

Treatment of Neuroses: Irritative neuroses are easily enough controlled, but if neglected almost invariably suggest to the patients the idea of over-dieting—the very worst thing they could do. Indeed, there are two chief factors in producing atony in these cases: (*a*) pyloric spasm, (*b*) over-dieting and malnutrition. One thing after another is cut off because of digestion distress until a diet is reached that is practically one of starvation. In these patients the amount of gastric distress does not seem to be dependent on either quantity or quality of food, and if the irritation of the stomach can be allayed by sedative treatment, the more they eat the better they seem to be. Early cases show the signs of nervous indigestion only, and unless careful physical examination is made, may be regarded entirely as such. This is unfortunate, because much valuable time is lost. If possible, diagnosis should be made, and treatment started before atony develops.

A combination of bromide gr. vi.-viii., chloral gr. iii., resorcin gr. iii., and chloroform water ʒ i. with gtt. vi. of spirits of anise ad ʒ iv. to disguise the taste, has seemed to be the most serviceable. Next in efficacy has appeared to me to be hyoscyamus extract.

The "Priessnitz umschlag," or Neptune girdle, is one of our most efficient means of soothing gastric irritability. Two layers of flannel, large enough to cover the entire abdomen, are wrung out of hot water as dry as possible, and covered with oiled silk. This is to be changed twice a day and can be worn constantly.

The internal application of galvanism, the anode being placed within the stomach, has been of great service. With the electrode which I have devised for this purpose, it is a simple procedure, and uniformly well borne by the patient.

Lastly, a certain amount of physical or mental rest is needed in nearly every case, amounting at times to the necessity of a thorough rest cure. It is especially important that the patient should not eat when overtired, but should rest one-half hour before meals.

To control motor spasm, (1) we reduce gastric hyperæsthesia in the lines just indicated; (2) we reduce the hyperacidity.

To reduce the hyperacidity, we may employ, in addition to the previous treatment: (*a*) Frequent feedings. It is still a mooted point whether an overabundance of nitrogenous food does not ultimately perpetuate the condition. My own preference is for mixed diet, without too large a proportion of meats. (*b*) Alkaline powders two hours after meals—bismuth subcarbonate, magnesia usta, magnesium carbonate, sodium bicarbonate, prepared chalk in varying proportions. (*c*) Nitrate of silver, either in gr. ss. doses before meals; or as spray 1:500 daily or 1:3,000 by lavage.

As cases illustrative of this treatment may be cited:

Case I.—Male, aged thirty-one years; neurasthenic, gastroptosis, mild atony, mild gastritis, subacidity, pyloric spasms, sensory derangements, spastic constipation. Diet consisted of two eggs, two pieces of toast, one cup of malted milk the day previous to examination.

On March 15th given bromide-chloral-resorcin-chloroform mixture. General diet except red meats, six meals daily, and the Priessnitz umschlag.

On April 10th, gained eight pounds, eating everything without symptoms. Bowels have been regular since the second day of treatment.

On May 10th, gained fifteen pounds more, making twenty-three pounds in eight weeks. Feels well, is able to do hard work, and has no symptoms; has not taken any medicine for three weeks.

Case II.—Female, aged forty-eight years; for ten years nausea, vomiting, pains, and general gastric distress. Gastroptosis, moderate atony, hyperacidity. Rest in bed; forced feeding, bromide-resorcin-chloral-and-chloroform mixture, Priessnitz umschlag, and intragastric faradism. Gained nineteen pounds in four weeks, and went home strong and free from symptoms.

When atony develops the abdominal belt should be constantly worn during the working hours, and great attention should be given to diet. There should be frequent small meals of concentrated nutritive power, given as dry as possible.

A sufficient amount of liquid should be given to prevent thirst, but no more. The proportions between the nitrogenous and non-nitrogenous ingredients should be determined, (1) by the amount of gastric acidity, (2) by the presence or absence of indicanuria. Exercise should be absolutely prohibited after meals. Spasm and secretory neuroses should be energetically treated. In atony, intragastric faradism has been of indispensable service; fifteen-minute séances three times a week for about a month are usually sufficient. Such treatment should be given about twice a year in advanced cases to obtain lasting results. Above all, the patient must be considered a poorly nourished neurasthenic, and treated accordingly.

Surgical treatment, from a medical point of view, is applicable only in cases of muscular insufficiency, with retention of food. Here a gastro-enterostomy is of service, as in cases of pyloric stenosis. Gastroplication and the operation for shortening the gastro-

hepatic ligaments may sound theoretically correct, but I doubt if on the whole they will prove satisfactory. Neither operation would be of the least benefit in pyloric spasm or arterio-mesenteric constriction, while gastroplication would hardly control even duodenal kinking.

Conclusions.—1. That in the great majority of cases an adequate cause for the gastroptosis is not discoverable.

2. That gastroptosis does not of itself, in an uncomplicated form, produce symptoms.

3. That the displacement of the stomach, however, is a predisposing cause of a variety of gastric neuroses, of sensation, motion, and secretion.

4. That these neuroses are usually induced by some definite mental or physical strain.

5. That the displacement of the stomach is a strong exciting cause for muscular atony; that atony is the most common cause for the symptoms presented.

6. That a complicating atony is associated with a more or less profound neurasthenia, and that a direct relation exists between these two conditions.

7. That gastric acidity is increased in direct proportion to the atony, unless counteracted by gastritis.

8. That mild degrees of gastritis are apt to occur in stomachs that are displaced, but the symptoms are neither severe nor persistent.

9. That gastritis occurring in atonic and displaced stomachs reduces the excessive acidity of these cases and seems to modify the severity of symptoms.

10. That atonic dilatation without mechanical hindrance is exceedingly rare.

11. That dilatation, or better, muscular insufficiency, may occur in gastroptosis from duodenal kinking, from arterio-mesenteric constriction, or from pyloric spasm.

12. That pyloric spasm is common in displaced atonic stomachs with hyperacidity, and may lead to a temporary dilatation.

13. That in a large number of cases, inattention to the conditions of atony, of neuroses, and of gastric secretions has led to an unsuitable, insufficient diet which reacts both on general nutrition and on local conditions within the stomach.

14. That surgical intervention is applicable only to the cases in which dilatation exists.

ON THE ANALOGY BETWEEN THE NERVOUS CONDUCTIBILITY AND THE ELECTRIC CONDUCTIBILITY, AND THEIR RELATION TO THE FUNCTIONAL NEUROSES.[1]

By A. D. ROCKWELL, A.M., M.D.,

NEW YORK.

The reproach of Mr. Lecky, that the medical powers of electricity, which of all known agencies bears the most resemblance to life, are unexplored, is no longer deserved.

It is true that as a remedial agent it has by no means kept pace with its unexampled development as a commercial power, and yet from the immeasurable amount of chaff that has flooded and still floods medical periodical literature both here and abroad can be winnowed many scientific facts of value, especially in the domain of body nutritive exchanges and the relation of electric to nerve conductibility. While the electric current and the nerve current are quite different in their essential characteristics, late researches have shown some very interesting and suggestive points of resemblance. The nerve tracts, which were formerly thought to be continuous, are now known to be made up of independent neurons, along which in their normal condition the nerve waves are propagated, or are arrested if there is a defect of continuity.

When the healthy nerve cell receives the stimulus of the nerve wave, energy is liberated, animating and reinforcing the nerve current. In the sick nerve cell, on the contrary, energy is not excited, much less increased. Without this reinforcement as developed in the healthy cell, the nerve wave can make no further progress. In other words, the neuron becomes impervious to it. Pathological conditions show that the conductibility of the neuron may be complete or incomplete according to the degree of permeability of the nervous tract. If the nerve current can pass it is translated into sensation, movement, intelligence. If it cannot pass and there are no gross structural changes, we get a variety of the functional neuroses, as hysteria and hysterical anæsthesia and paraplegia, forms of neurasthenia, and mental defects as shown more especially in confusion of ideas and impaired memory. In order to make clear the striking analogy between the nerve current and the electric current, it will be necessary to refer briefly to a novel and very interesting contrivance called the "coherer," an essential part of the outfit for wireless telegraphy. This coherer is simply a tube of metallic filings.

Now, although metal is the best of conductors, yet when it is divided into separate and distinct particles like the filings of iron, the coherer which is made up of these filings becomes non-conducting to a weak current. If, however, the tube containing the filings is placed in a solenoid through which course currents of high frequency, or in the range of influence of the cathodic ray, the tube immediately becomes a conductor and the current passes; or if it is placed in proximity to a static machine in operation, the electric waves set in motion by the electric sparks strike the coherer and render it immediately a conductor.

It immediately becomes non-conducting again, if subjected to any shock however slight. Removed from these influences, it gradually loses its conductibility, retaining it longer under the influence of cold than of heat. These invisible and silent waves of influence nothing can obstruct or deflect, and in the far distance —the limit of which no one can yet say—striking the tube of iron filings, are translated into signs of intelligence.

In order to study a phenomenon with advantage it is well to have a theory, and although the theory be defective, it yet gives us a point of departure, leading, it may be, to a clearer conception of the principles involved. This theory, as suggested by M. Branly, to whom we are indebted for this interesting discovery, supposes that each grain is surrounded by a sheath of condensed ether, but not in contact the one with the other. The waves of an electric discharge expand these sheaths of ether, and it is their mutual penetration that changes the tube of filings from a non-conductor to a conductor. A shock retracts these sheaths and destroys their conductibility.

On the other hand, when we study the nervous system on the basis of the neuron theory we find analogies of the most striking character.

Neuro-motor energy may be developed primarily in the nerve centres, or it may come from without, external physical energy being transformed into reflex nervous energy; in either case it overcomes the natural resistance of the independent neurons, making them conductors of energy in the same way that the electric wave generated at a distance, and striking the disconnected filings of the coherer, overcomes its natural resistance and makes it a conductor.

The neuron with its dendrites makes up the central and active part of the nerve cell, the cylinder axis

[1] Read at the annual meeting of the New York Medical Association, held in New York, October 10, 1900.

prolongations acting as conductors of the nervous current. Under the influence of external irritation the dendrites are increased and developed, and the greater the activity of the neuron the greater the tendency to produce new protoplasmic growths. Does not this harmonize very closely with the working-theory in explanation of the action of electricity on the disconnected conductors of the coherer—the expansion and contraction of the ether surrounding each metal particle corresponding to the increase and development or the decrease and obliteration of the protoplasmic prolongations of the cell? The points of contact are broken between the individual neurons, and the nervous wave is arrested in its course.

This theory of the alternating conductibility and non-conductibility of the disconnected conductor termed the coherer, and the theory of the neuron open up to us not only the possibility of understanding more clearly the gross changes of organic lesions of the brain and the invisible anomalies of structure that we term nutritional, but throw a new and brighter light on the rationale of the well-established value of electricity in the cure of so many functional diseases of the nervous system, and the relief often afforded even in diseases that are organic and structural.

Reasoning from analogy and the results of physical and physiological experiment, it is natural to conclude that conditions such as hysteria and hysterical anæsthesia and paraplegia, forms of neurasthenia, and various mental conditions, are the derangements in which electricity in some one of its manifestations is specially indicated. But long before we possessed any knowledge of these interesting facts relative to nerve and electric conduction, the clinic had assured us positively and repeatedly of the efficiency of this method of treatment in the functional diseases of the nervous system. One case bearing on this point I beg leave to offer as illustrating not only the analogy between the nervous conductibility and the electric conductibility, but as practical evidence of the power of electricity to restore the conductibility of the neuron that had become resistant to the nerve current.

Such a result as the one about to be related is sometimes spoken of as one of the brilliant results of electrical treatment. It was a brilliant result only in so far as it was a quick result. Nature was simply reinforced and was enabled to accomplish at once what she was slowly trying to do, and what she would in all probability have succeeded in doing if left to herself.

Miss ——, aged twenty-four years, whom I had treated many times some two years previously for a nervous derangement, and who had in great measure recovered, came under my care again in the autumn of 1899 in a deplorable state of mind and body, the result of a nervous shock in escaping from a burning building. Up to this date she had been for some time in better health than ever before, but evidences of her hereditary and acquired nervousness, or nervelessness, were never altogether wanting. She suffered more or less at all times from morbid fears, and had formerly been able to take an unusually large quantity of stimulants without appreciable effect.

During the worst periods of her combined hysterical and neurasthenic attacks, an ordinary claret glass of brandy would affect her seemingly no more than so much water.

As her condition improved this insusceptibility became less and less marked, until finally she was influenced by stimulants almost if not quite as readily as others. After the great shock of the fire this craving and remarkable capacity for intoxicants again returned, and was associated with confusion of ideas, impaired memory, partial paraplegia with anæsthesia, and profound mental depression relieved by violent paroxysms of weeping. Her amnesia was peculiar in that it related to a few things only. Passing events, and the ordinary occurrences of the day were well remembered; but, for example, she claimed to be unable to remember ever having been to my office. I might have ascribed this to caprice, excepting that her mental failure was distinctly pronounced in other ways, Under nerve sedatives she was temporarily quieted. and during the next ten days improved a little, but only a little, in her general and special symptoms, sufficient to be brought to the office in a carriage.

She was immediately placed in what may be termed an electro-static, vibratory field. More specifically she was placed on an insulated stool, and connected with the positive pole of the apparatus. The negative pole was grounded and the spark gap regulated at two inches, giving to the patient vibratory waves very distinct, but altogether agreeable. I lay especial stress on this point. If she had been simply placed on the usual insulating platform and given the ordinary treatment of static electrification, the nerve tracts would not have been influenced by those currents of vibratory, alternating potential that are so essential in restoring conductibility to the "coherer" in the operation of wireless telegraphy to which allusion has been made.

I must not forget to say that the tactile sensibility of the patient was carefully interrogated, but the æsthesiometer proved of little value, since the anæsthesia of the tips of the fingers and of the body generally was so profound that the prick of a pin was not felt. Only at the tip of the tongue was there any sensation. Here a prick was felt, but the two points of the æsthesiometer were separately felt only when apart some 3 mm.

A single séance of fifteen minutes resulted in a very remarkable amelioration of several symptoms, notably of the anæsthesia, and within a week, after three additional treatments, she was able to walk alone with considerable ease. She had quiet, restful nights for the first time since the accident, and arose refreshed and cheerful. Her amnesia quite passed away, the fingers were ordinarily sensitive to touch, and at the tip of the tongue she was able to discriminate the points of the æsthesiometer when but little more than 1 mm. apart.

A most interesting evidence of improvement was the disappearance of desire for and the insusceptibility to stimulants.

As a clinical fact the foregoing case by no means stands alone, and doubtless could be duplicated in its essential features by any neurologist who makes much use of electricity in medicine. Not only have there been many quick recoveries in cases of profound functional nervous disorders by placing patients within the field of the influence of currents of high potential and high frequency, but it is even true that some violent neuro-motor excitation, such, for example, as a sudden fright, anger, and even joy, has restored power to the paralyzed limbs of hysterical patients by overcoming the non-conductibility of the resistant neuron.

In order to explain the sudden change of the coherer, as the tube of iron filings is called, from a non-conductor to a conductor, recourse was had to the theory of a sheath of ether surrounding each particle, whose alternate expansion and contraction under electric influence and shock changed entirely its power of conduction. In dealing, however, with the relation of electric energy and shock to the nervous system, we find in the physiology and minute anatomy of its structure a basis of knowledge rather than theory. We are told that the nervous system is composed of independent neurons, and that the connection between them is made by simple contact of the cylinder axis of one neuron with the protoplasmic prolongation of another.

The readiness with which the nervous current flows,

translating itself into sensation, movement, and intelligence, depends upon the functional integrity of the neuron and the perfection of its collateral connections. The contact between the dendrites of one neuron with the protoplasmic prolongations of another must not only be constant, but must be constantly changing in order to make a way for new ideas and new impressions. In the normal condition of mind and body there is no severance between the dendrites and cylinder-axis fibres, but in impairment of the psychic function, whether it registers itself in the domain of sensation, movement, or intelligence, or in all these as in the case just related, these ties or points of contact become impaired or altogether broken.

Electricity and all energy are amenable to the law of the correlation and conservation of forces. As iron becomes magnetized or heated by the application of force or heat, so the electric energy applied to the human body is not lost, but in its transformation tends in a single direction, the stimulation of the living molecule and the nourishment of the nerve centres, the depository and dispensers of all vital energy. It calms the irritable cell and increases its activity when sluggish.

The modification that an organic compound undergoes when subjected to the action of a physical force varies, of course, with its intensity, and especially with the nature of the body on which it acts. When the compound is a metal, the passage of a current of sufficient power generates heat and dilates its constituent molecules. When the electrolyte is a living body, the heat generated is not primary but secondary.

Caloric is not directly absorbed as in the former case, but the elevation of temperature results from biological changes of a secondary nature, and this conservatism is indicated by a quickened circulation and an increased activity of all the excretory and secretory processes of the body. The increase in the elimination of urea and all toxic products, now so well established, through the influence of currents of high tension and high frequency, acts in two ways: First, "as a reflex of defence against the action upon the system of these toxic products suddenly set free"; second, by hastening and increasing the nutritive exchanges throughout the body.

Admitting, as has been claimed, that inherently electricity has neither curative nor destructive qualities, yet it is the bearer of energy both mechanical and chemical. It has to do with molecules and atoms, shaking them apart or permitting new arrangements, and the benefit or injury that comes to the organism through this disturbing process depends upon the rôle played in the economy by these new atomic arrangements. As to the underlying causative factor in the field of the functional neuroses, we can arrive at but one conclusion, namely, that it is an impairment or interruption of the potential energy of the cell life.

We have seen how physical shock, or the stress and strain put upon the nervous system by the dissipations and even the legitimate demands of our modern civilization, interferes with the vital function of the neuron and renders it impervious to the nerve wave.

We have seen also, on the other hand, how the subtle electric waves generated by currents of high tension and high frequency, so analogous in some respects, and yet so entirely different in nature from the nervous current, have power to restore the interrupted conductibility of the nerve tracts. The inherent energy of the nerve cells is liberated, new paths of conduction form, resulting in modification of motor, sensory, secretory, excretory, and vasomotor processes.

It cannot, therefore, be too often repeated that the fundamental idea of the therapeutic value of electricity is its influence on the nerve cell and on general and local nutrition.

THE TREATMENT OF TYPHOID FEVER AT THE NEW YORK HOSPITAL.

By FREDERICK L. KEAYS, M.D.,

HOUSE PHYSICIAN, NEW YORK HOSPITAL.

In this article no attempt will be made to deal exhaustively with the subject of the treatment of typhoid fever. It is intended to outline as briefly as possible the treatment employed at the New York Hospital. It seems convenient to consider, 1st, the treatment of an uncomplicated case; 2d, the treatment of the various complications; 3d, the subject of feeding; 4th, the management of the patient during convalescence, and 5th, the prophylactic treatment.

I. The Treatment of an Uncomplicated Case.—As the treatment is altogether symptomatic we will take up the different systems of the body, and give the treatment of symptoms arising under these heads.

1. The Nervous System. (*a*) Fever: This symptom is treated almost entirely by tub baths. The baths, as employed here, differ somewhat under the different attending physicians. One gives them every three hours for a temperature of 102.6° F. or over, the bath being at a temperature of 65° and lasting for ten minutes. The others make the bathing temperature 103° or over, starting the bath at a temperature of 80°, and diminishing it in the two or three following baths to 70°. In all cases, unless the temperature of the patient runs a high course or the nervous symptoms are pronounced, the baths are omitted at 11 o'clock P.M. and at 2 o'clock A.M. Of course these are not hard-and-fast rules, the temperature, as well as the duration of the baths, being modified to suit various cases. A child may react well to a bath at 80° lasting for five minutes, while a strong, alcoholic patient may require fifteen minutes of a bath at 65° or even 60°. Throughout the bath all parts of the patient's body are rubbed by two assistants and cold water is applied to the head from time to time. The condition of the patient is noted during the bath, and if any symptom of heart failure should appear he is taken out; moderate degrees of cyanosis or shivering, which so often follow the bath, are not considered contraindications to bathing for the full time. It is customary, after the bath, to give the patient a glass of warm milk, and even to place hot-water bottles at the feet if the blueness and shivering continue. Compound capsicum mixture (tr. capsici, ♏ iiss.; tr. zingiberis, ♏ viiss.; chloroformi, ♏ iiss.; spir. frumenti, q.s. ad ℥ ii.) is often used after the baths to "warm up" the patient. In cases in which complications contraindicate tub bathing, and often when the patient is heavy enough to be unwieldy, alcohol sponges are substituted for the baths, the alcohol being cooled by ice. A modification of the alcohol sponge, which has been used here with good effect, is to have one person sprinkle the patient's body with alcohol by means of a whisk broom, while another hastens evaporation by waving a fan. The alcohol sponges have been found

nearly as efficient as the baths, although their general stimulating effect seems less marked. In some cases, when the temperature does not react well, especially when sponges are being used, small doses of phenacetin or acetanilid are given every three hours for bath temperatures, and no bad effect upon the pulse has been noticed. One patient, who had a large granulating wound of the thigh, ran a course of typhoid very comfortably with gr. iii. doses of acetanilid every three hours when the temperature was 103° or over, an ice coil being kept all the time upon the abdomen. It is needless to say that the reduction of temperature is only one indication for the baths. They are used just as much to control the other nervous symptoms, as for their general tonic effect. The value of baths in typhoid fever is now so generally accepted that it is unnecessary to argue in their favor. After seeing them used, we can say with certainty that they rob typhoid of most of its unpleasant symptoms. Patients running bath temperatures are covered by a sheet only, unless they complain especially of cold, when blankets are added. In cases in which there is an afternoon rise of temperature during the period of convalescence, quinine sulphate is given, about fifteen grains a day, provided no obvious cause for the temperature can be found. If this does not reduce the temperature, and if it seems certain from the absence of all symptoms that the active process of the disease has ceased, the patient's food is increased, and he is gotten out of bed. Under this treatment the temperature soon subsides.

(*b*) Headache: When this symptom, which is seen usually in the first weeks of the disease, is not relieved by the baths, sodium bromide in gr. xv.–xxx. doses is given. Phenacetin and acetanilid, the latter usually in the form of the compound acetanilid tablet, are also used. Continual application of cold to the head, by means of the ice cap, is employed with relief in some cases.

(*c*) Sleeplessness: This symptom, like headache, is most common in the early days of typhoid and is often stopped by the baths. When this is not the case any of the mild hypnotics are used, perhaps most often trional in gr. x.–xx. doses, given in hot milk. Sodium bromide is used with the double purpose of producing sleep and relieving headache. Sometimes a half-grain of codeine is given with trional, a combination which has usually proved very efficient. Morphine is never used.

(*d*) Delirium: With the use of baths, except in alcoholic cases or in neglected patients who are well along in the disease, this symptom is seldom seen in other than its mild forms. In the mild cases of delirium, sodium bromide or other weak hypnotics are often sufficient. The whiskey used for stimulation has a quieting effect in many cases. In severe forms of delirium, seen chiefly in alcoholic patients, more frequent bathing is used, that is, the baths are continued through the night. In alcoholic delirium larger doses of whiskey are given, one ounce or even more, every three hours. Continuous doses of sodium bromide are also given, and if the pulse permits, small doses of chloral hydrate are added. Paraldehyde and amylene hydrate often work well, and their unpleasant taste and the danger of upsetting the stomach are overcome by giving them by rectum in warm milk, double the ordinary mouth dose being used. An alcoholic case can sometimes be quieted by substituting for an evening bath a cold pack of from fifteen to forty-five minutes' duration. Delirious patients are secured in bed by draw sheets, and when the delirium is violent their hands and feet are tied to the bed, unless they can be constantly watched.

2. The Digestive System. (*a*) The Mouth: Each patient is ordered a mouth wash, made by adding tr. of myrrh ʒ i. and sodium bicarbonate gr. xxx. to water ℥ iv. The mouth is thoroughly swabbed out with this at frequent intervals, usually after each feeding. This precaution prevents such unpleasant complications as parotitis and otitis media. The tongue, when dry, is moistened frequently with benzoinated oil or with compound syrup of hypophosphites.

(*b*) Nausea and vomiting: When nausea is complained of, the food is modified. Prepared milk, made by adding cerium oxalate gr. v. and sodium bicarbonate gr. x. to ℥ viii. of milk, or peptonized milk is given. If the nausea still persists or if vomiting ensues, the various gastric sedatives are employed, such as minim doses of dilute hydrocyanic acid, nitric acid ♏ ¼ to water ʒ i., frequently repeated, or small quantities of wine of ipecac or of tartar emetic. Frequent feedings of small quantities of peptonized milk, say ʒ i. or even less, every hour will sometimes settle the stomach. Counter-irritation over the epigastrium by means of a mustard paste proves beneficial in some cases. When all these means fail, and they often do, gastric lavage is done, food is withheld for several hours, and then the feeding is begun in small quantities, gradually increased.

(*c*) Constipation: In the early days of the disease the bowels are kept well open by means of calomel in small doses, followed by saline purgatives. In the second and third weeks, when there is danger of intestinal complications, no cathartics are given, the bowels being moved, when necessary, by means of glycerin suppositories or soap-suds enemata.

(*d*) Diarrhœa: When there are frequent small movements, the condition may be the result of constipation and is relieved by means of a large enema which washes out the lower bowel. If we are sure that the diarrhœa is not due to fecal impaction, mild astringents, such as bismuth subnitrate or tannalbin, are used. In severe or protracted cases, small doses of powdered opium are given.

(*e*) Distention: This symptom is generally treated by means of enemata containing turpentine in small quantities (ʒ ss.–ʒ i.) The rectal tube is also used, especially after the enemata. Sometimes several small doses of turpentine (♏ v.–x.) in capsules are given with benefit. Turpentine stupes are also used. Except in neglected cases, this symptom is seldom troublesome. There seems to be no doubt that the prevention of marked abdominal distention does much toward lessening the danger of such serious complications as intestinal hemorrhage and perforation.

3. Circulatory System. With the baths some cases pass through their whole course without indications for further stimulation. When the pulse becomes rapid, soft, dicrotic, or intermittent, whiskey is given in three or four half-ounce doses a day at first, increased to six or eight doses, as the pulse requires. Except in alcoholic cases, more whiskey than this is seldom used. In some persons, whose stomachs do not tolerate whiskey, brandy is substitued to advantage. Brandy might also be used for stimulation when there is diarrhœa. When whiskey or brandy alone fail to hold the pulse, strychnine sulphate is added, and if still more stimulation is needed digitalis is given either as the tincture or as the fluid extract.

4. Respiratory System. The mild forms of bronchitis, which usually accompany typhoid, are disregarded in treatments. Bronchitis is not made a contraindication for tub bathing, in fact the bathing often appears to improve this condition. If the bronchitis becomes extensive or troublesome the ordinary remedies are employed, such as brown mixture, Stokes' expectorant, or Delafield's bronchitis tablets.

5. Urinary System. During the active stage of the disease the urine is measured and a record kept. A specimen of urine is examined every three days, un-

less more frequent examination is required. When the quantity of urine passed is small, or if the specific gravity is high, patients are encouraged to drink more fluids, either water or Vichy. The ordinary mild forms of acute degenerative nephritis are disregarded in treatment. Retention of urine, if not yielding to the ordinary remedies, such as heat over the bladder, hot enemata, and sweet spirits of nitre, is relieved by catheterization, repeated if necessary.

II. The Treatment of Complications.

1. Intestinal hemorrhage: When blood appears in the stools, if it is found not to come from the rectum, the tubs are discontinued; the patient is kept as quiet as possible, Magendie's solution of morphine being used if necessary; and continual application of cold is made to the abdomen by means of the ice coil. The temperature, if high, is kept down by alcohol sponges, given without turning the patient, and by antipyretics. If the hemorrhage is severe enough to produce symptoms, the foot of the bed is raised, hot saline enemata of about eight ounces each are given at intervals of from three to four hours and stimulation is increased. If these means are insufficient, the patient is infused with hot saline solution. Hot water bottles are used to keep up body temperature if it falls below normal.

2. Pneumonia: Should a pneumonia intervene in the course of typhoid, the treatment is modified only in so far as new symptoms referable to the pneumonia arise. The tubs are kept up, unless the condition of the patient is such as to make them immediately dangerous. If tubs seem inadvisable and the nervous symptoms still need treatment, sponges are substituted. In the advent of heart failure, more active stimulation is employed. Œdema of the lungs is met as in pneumonia by nitroglycerin, dry cupping, and oxygen inhalations.

3. Nephritis: If a severe nephritis arises, appropriate treatment is added. Tension in the pulse is combated by nitroglycerin or chloral hydrate. Diminished excretion of urine is treated by diuretics, hot saline enemata, or hot rectal irrigations with the Kemp tube. The baths are stopped and the temperature is reduced, if necessary, by means of antipyretics.

4. Phlebitis: The limb affected is kept as quiet as possible. The most efficient treatment perhaps has been the application of twenty-five-per-cent. ichthyol ointment to the course of the vein involved. Wet carbolic dressings are also used. Tincture of iodine is sometimes painted over the affected vein, and dressings of lead-and-opium wash give relief to the pain in some cases.

5. Bed sores: The treatment of these is chiefly preventive. Each patient's back, shoulders, and hips are rubbed daily with a paste made from zinc oxide with fifty-per-cent. alcohol. Reddened areas are protected by dressings and by rubber rings. If these measures are inadequate the patient is placed upon a water or air mattress. If bed sores do form, dead tissue is cut away, and various antiseptic and stimulating dressings are applied. Twenty-five-per-cent. ichthyol ointment has been found efficient for cleaning up these sores and starting granulations.

It is hardly necessary in this article to give the treatment of such rare complications as intestinal perforation, neuritis, periostitis, and osteo-myelitis.

III. Feeding.—The routine diet throughout the active stage of typhoid is milk, fifty to seventy ounces being given in twenty-four hours. It is customary to keep a daily record of the amount of milk taken, so that it will not fall below what is necessary. When plain milk is not acceptable to the patient it is varied in different ways; a little brandy or a few spoonfuls of coffee or some malted milk is added; koumyss or matzoon is substituted for milk from time to time for variety. Patients who complain of hunger are given broths and beef juice. As soon as the temperature reaches normal, more active feeding is begun. The patient is given a lamb chop, or an egg boiled for twenty minutes, and finely chopped, or scraped-beef sandwiches. Proper mastication of the food is urged. Each day, as the food agrees, new articles of diet are added to the list, or those already given are increased in amount. Baked custard, bread, milk toast, and finally chicken, raw oysters, baked apple, baked potato, rice, hominy, and green vegetables are allowed, the milk all the time being cut down. The patient is kept upon this food while in the hospital and is told to continue it for several weeks after leaving.

IV. Management of Patient in Convalescence.—(*a*) Medication: Stimulants, which have been used, are cut down as fast as the pulse warrants. Two or three half-ounce doses of whiskey are usually given for some days, and then one or two egg-nogs a day, if the patient likes them. If tonics are indicated, small doses of strychnine sulphate, tincture of nux vomica, or iron, the latter often in the form of citrate of iron, and quinine, are administered; but good feeding and plenty of sleep are chiefly relied upon to build up the patient. The bowels are kept well open by means of mild cathartics such as calomel in small doses, cascara sagrada, aloin-belladonna-and-strychnine tablets, and the various saline purgatives. Calomel is used especially in the early days of convalescence to clean up the tongue. In general just as little medicine as possible is given.

(*b*) Getting the patient up: After several days of normal temperature, the head of the bed is raised, the height and time of raising being gradually increased. At the end of about ten days of normal temperature, the patient is allowed to sit up for from a half to one hour. If there are any signs of weakness the time is cut short. The time of sitting up is increased about an hour a day, until the patient can stand eight or ten hours, when he is given his clothes. Meanwhile walking has been tried and increased as strength allows. After about three weeks of normal temperature the patient is discharged.

V. Prophylactic Treatment.—All utensils used in the care of typhoid patients are marked and are employed only for such patients. Their bedding is carbolized before going to the laundry, where it is washed separately. The dejecta are treated with a strong solution of formaldehyde before being thrown into the sinks. Patients who are suspected of having typhoid are put upon individual enteric precautions until the diagnosis is cleared up. The utensils for these patients are marked with their names and are used only for them. Nurses and orderlies having the care of typhoid patients are told the danger of infecting themselves as well as others. They are instructed to disinfect their hands carefully after caring for enteric cases, especially after carrying bed pans, changing bedding, or giving tubs.

Kernig's Sign and Meningism. — Paolo Galli reaches the following conclusions: (1) Kernig's sign exists only in meningitis, whether this be of epidemic, secondary, or tuberculous origin. (2) It is a symptom of great importance, being found in 83.5 to 80 per cent. of cases. (3) As it gives us information in regard to the pressure of the cephalo-rachidian fluid, it may in regard to meningism be of value in differentiating simple dynamic disturbances from a true meningeal inflammation. Its presence, if positively ascertained, may take the place of lumbar puncture in the generic diagnosis of meningitis.—*Rivista Critica di Clinica Medica*, October 13 and 20, 1900.

A FEW REMARKS RELATIVE TO TYPHOID FEEDING.[1]

By WILLIAM M. BROWN, M.D.,

ROCHESTER, N. Y.

While the subject of this paper is one on which much has been said in the past, and of which it may seem that the ground has been well covered, yet I believe that the last word has not been said, and that the rule now so commonly observed, that a patient suffering from typhoid infection should have exclusively liquid diet until the temperature has been normal for a week, will soon become the exception.

Before entering on the subject proper I wish to emphasize that my position is not one dogmatic or that I would expect the ideas advanced in this article to apply to all cases alike. I feel that no physician has the right to subject each patient to an empirical rule; rather is it his highest duty to give the most careful consideration to the personal element in each case. Pre-eminently should this be so in typhoid and notoriously have we in the past failed to observe this obligation.

It has been stated to us by one of the prominent members of the profession that the "mortality rate and the prominent symptoms of hemorrhage and distension in typhoid fever are not essentially influenced by the diet."

While we realize that the large increase in body temperature, which is usually observed in typhoid, is the result of the toxæmia—this hyperpyrexia being caused in part by the irritation of the thermic centres by the toxins which result from the growth of the bacillus typhosus—yet we believe that the toxins from the specific bacillus are only a part of the cause. We remember that many other forms of bacterial life find a fertile field of culture in a large residue of partially digested food, and that the typhoid lesions with a turgid intestinal mucus membrane offer ideal opportunities for the absorption of their toxins, and further, that the mal-decomposition of the food residue is very largely responsible for the distention so often seen in typhoid-fever patients.

I repeat that typhoid fever is a toxæmia from the growth of a specific bacillus plus other forms of bacterial life, the secondary toxæmia developing after the specific.

Another consideration in arranging the diet for a typhoid patient is the influence of food and its digestion on heat production, which though slight may be decisive.

The ordinary source of animal heat is in the potential energy of the organic foodstuffs. This energy may be converted into heat directly, as the immediate results of chemical decomposition, which is about ninety per cent., and indirectly as by the mechanical movements, such as muscular contraction, blood flow, etc., which is about ten per cent. In a direct way one gram of proteids yields 4,937 calories, and one gram of carbohydrates yields 4,116 calories, while one gram of fat yields 9,312 calories. All structures produce more heat during activity than during rest, and the glands are the greatest heat-producing structures in the body; when muscles are contracting eighty per cent. of the energy expended results in heat, while only twenty per cent. results in work.

Now if you will keep in your minds the foregoing facts, we will consider for a few moments some of the physiology of the digestive functions.

The method of production of a digestive secretion is essentially the same, whether it be saliva, the gastric, the pancreatic, or the intestinal fluid, and consists of a nerve stimulation which is followed by a production of the special fluid of the gland supplied by the nerves so stimulated. These glands are composed of cells which during rest have a granular appearance throughout their structure. When stimulation is applied to the nerves supplying a gland of this kind, whether the stimulus is direct or reflex, the cells begin to lose their granular appearance from the outer border, and if the stimulation is continued the granules almost entirely disappear, having been used up in the formation of the secretion. Now while this stimulation produces a secretion in which the water and salts maintain a more or less constant relation, the organic constituents, those parts of the secretion on which depends its effectiveness, *e.g.*, ptyalin in the saliva, pepsin in the gastric juice, etc., are dependent very largely on the condition of the gland; *i.e.*, if the gland has been inactive, is unfatigued, the stimulation is followed by a secretion in which the percentage of the organic parts rises way out of all poportion to the water and salts, while, on the other hand, if the gland is fatigued the stimulus will have very slight or no effect on the organic parts, and the result is a secretion deficient in the constituent enzymes. Khigine has published tables which show that a diet rich in proteids promotes the greatest flow of the digestive secretions, but that a rich carbohydrate diet promotes a secretion with the highest digestive power.

Time will not permit me to go into details of the chemistry of digestion. The process is both mechanical and chemical, and both processes are decided heat producers, and also during functional activity of the digestive glands the constituent enzymes, which are derived from the cell contents of these glands, are used up, and it takes considerable rest for those cells to regain a condition in which they are able to furnish an effective digestive fluid.

It has been stated that in typhoid fever the various digestive fluids are deficient in both quantity and quality. The reason for this seems plain. The toxins resulting from bacterial life are very powerful chemical irritants, and any irritant introduced into the alimentary canal stimulates the digestive glands and results in their exhaustion. The restoration of the digestive efficiency should be one of the principal objects of our therapy. Give the digestive function enough rest so that when needed it will respond. Eliminate, so far as possible, the bacterial life in the intestine which will reduce the toxæmia. Give food which has been shown to increase the quantity and power of the secretions; viz., proteid and carbohydrate. Such food will leave but little residue as a bacterial culture medium.

Overfeeding or too frequent feeding fatigues the digestive glands. The secretions are inefficient and the food is but partially digested. That portion which is not prepared for absorption undergoes mal-decomposition, ferments, distention occurs, bacteria of all kinds find a mellow soil, and the toxæmia is increased, and too often only death steps in to disturb the deplorable cycle of cause and effect.

"It is not so much solid food as the indigestible which should be eschewed, and it should never be forgotten that all foods, except such as have been predigested, are solid in the first stage of digestion." A pint of milk contains as much solid material as a mutton chop and will take as long to digest. If all food is thoroughly disintegrated before entering the intestine we need have no fear of mechanical irritation to ulcerating surfaces.

The preparation of a diet list for each typhoid patient is a problem which must be solved at the bedside; but, in consideration of the physiological facts before stated, is it not logical to give these patients a more liberal diet, rich in proteids and carbohydrates and at longer intervals than have prevailed in the past? If the food is not efficiently digested, supple-

[1] Read before the Monroe County Medical Society, 1900.

ment with artificial digestion. Give acidulated beverages, which relieve thirst and aid digestion. Water favors nutrition and the elimination of wastes and toxins, and also aids in the dissipation of heat.

A clean tongue, a soft abdomen, natural stools not too hard and without coagula of casein or flakes of fat, show that milk if taken is being well digested and is proper food; but, on the other hand, milk with its large proportion of fat is not easily digested by many people, and should be given with caution and close observation in typhoid. I think that a "typhoid stool," so called, is a partially digested milk stool. We do not observe the typhoid stool from patients not fed on milk.

During the past two years medical literature has recorded many experiments of the more liberal feeding of typhoid-fever patients, and in each instance there has been conclusive evidence of its value.

In conclusion the facts are: 1st. That the bacillus typhosus while the initial is not the prepondering factor in the toxæmia.

2d. That in ordinary cases the functions of digestion are attended by heat production, which is varied in amount by the kind of food ingested, proteids and carbohydrates giving the least number of heat units while promoting the most effective digestive fluids.

3d. That the process of digestive secretion is accompanied by a transudation of certain portions of the cell substance in the various glands, which require considerable time for restoration before they are capable of efficient work. Hence we should not feed too often.

4th. That an inefficient digestion leaves a large residue of food which undergoes fermentation, causes distention, increases the danger of hemorrhage and perforation; also forms a favorable culture medium for the various bacteria, so increasing the toxæmia, which in turn hastens the disintegration.

5th. That milk unprepared is not a liquid food and will take as long to digest as many solid foods.

A Note on the Causation of Breathlessness in Anæmic Debility.—J. Henton White says that so far the established facts of anæmia show that a considerable strain is thrown on the right ventricle and pulmonary artery, and that there is a systemic vasomotor paresis. Granted that there is a supply of vaso-constrictor fibres to the lungs, it seems obvious that under normal conditions, when venous blood stimulates the medulla, the impulses to the respiratory centre and the heart would be assisted by a dilatation of the pulmonary vessels, which would be brought about by an inhibition of the vaso-constrictor impulses which are constantly travelling along all vaso-constrictor nerves. In anæmic debility, however, the dilatation of arterioles is delayed; this being the case in the pulmonary system, all the extra blood which has to be forced through the lungs on exertion must depend on right-ventricle force, unassisted, as in health, by a dilated periphery. As supporting the explanation of anæmic dyspnœa by vasomotor failure, it is to be noted that the disease is prevalent in the female sex, whose vasomotor system is more unstable than that of the male, and also that it usually occurs at puberty, when this system is unusually active.—*The Birmingham Medical Review*, October, 1900.

Antitoxin in Cerebro-Spinal Meningitis.—Francis M. O'Gorman was called to see a child which was evidently suffering from broncho-pneumonia and laryngeal diphtheria. He injected 1,000 units of anti-diphtheritic serum. In two hours the temperature had fallen to 103° F., the respirations to 86, and the convulsions had almost ceased, but the pulse remained at 190. Five hundred units additional were injected, and the breathing became easier. The next day breathing was again difficult, and 1,000 units were injected in the morning, 500 in the afternoon, with beneficial results. For weeks the illness continued, but the child constantly improved. The pulse, however, remained between 150 and 182 for a fortnight and then fell to 140, where it stayed. For two months the child was in excellent health, and then suddenly had violent convulsions. Cerebro-spinal meningitis was diagnosed. The child died within two days. The author believes that the extraordinary pulse and respiration of the previous illness were due to a latent inherited meningeal inflammation. Antitoxin had a decidedly beneficial action upon the convulsions in the previous attack, and the author queries whether its administration might have saved the child's life in the second attack.—*Buffalo Medical Journal*, October, 1900.

Contagious Insanity ("Folie à trois" and "Folie à deux").—E. P. Chagnon says that the popular idea that insanity is contagious is true only under certain circumstances. The persons must live the same family life, possess the same ideas and sentiments, live out of the pale of external influences. Moreover, one of the two, the one playing the active rôle, must by means of superior intelligence, energy, and dominating will power, be able to impress upon the passive nature the probability of the delusions which have emanated from his or her diseased brain. The author reports a case of delirium shared by three seamstresses who had lived together for years, and another of delusions held by a brother and sister who had lived together for fifty years.—*L'Union médicale du Canada*, September, 1900.

Acute Fibrinous Bronchitis due to Influenza.—Luigi Masciangioli reports a case of this affection, which he says is rare enough as a primary disease, and altogether exceptional as a complication of any other disease. In the case under discussion the usual symptoms, cough and dyspnœa, were absent. There were sopor almost from the onset of the influenza, and a bronchial souffle at the apex of the right lung, with other indications of grave functional disturbance. The diagnosis was difficult, but was cleared by the appearance of fibrinous sputum. It was evident that a considerable number of the bronchial branches had become rapidly occluded, causing collapse of a large amount of pulmonary parenchyma, with consequent accumulation of carbonic acid in the system; hence the symptoms of depression. Treatment consisted of the usual remedies, followed by pulmonary gymnastics with the inhalation of disinfectant and balsamic preparations.—*La Riforma Medica*, September 27, 1900.

Delirium in the Course of Infective Diseases.—Luigi Silvagni thus concludes his study of this subject: The appearance of delirium during the course of infective diseases is a frequent symptom to which certain individuals are predisposed through hereditary nervous taint, concomitant functional neuroses, alcoholism, or extreme physical or mental fatigue. The differential diagnosis between infective or temporary toxic delirium and a true psychosis is extremely difficult, but we must bear in mind that real insanity is most rare in the course of febrile diseases; that the origin of the delirium in these cases is very complex (hyperpyrexia, intoxication, inanition, etc.), and that infective delirium being under no special rule, but able to assume any form of the disorder, may be more under the influence of special mental tendencies on the part of the patient than that of the infective process.—*Rivista Critica di Clinica Medica*, September 22 and 29, and October 6, 1900.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM WOOD & CO., 51 Fifth Avenue.

New York, December 1, 1900.

THE NEED OF A FILTRATION PLANT FOR OUR WATER SYSTEM.

Now that the grand jury has taken up the question of a purer and more abundant water supply for Greater New York, there is a reasonably good prospect that some very necessary reforms along desirable lines will be instituted. Up to the time of the recent rainfall, the higher portions of the beds of the water-sheds have been exposed and the lighter showers have washed decaying vegetation and other forms of organic débris into the general currents of the entire water system. As a natural result there has been a public clamor for some guarantee against what is of almost constant occurrence under the usual conditions of prolonged drought. It is useless for the authorities, in view of their present helplessness in fighting against natural causes, to urge that there is no marked increase of sickness as the result of the state of affairs in question, inasmuch as it is extremely difficult to persuade the people that filthy water as such, because it may not carry with it typhoid germs, is a tolerable infliction which must be complacently borne. The cry is not only for safe water, but for pure water.

Much of the trouble in the districts supplied directly from the larger mains is due to the stagnation deposits in what are styled the "dead ends" of the fire plugs. These cul-de-sacs not only afford favorable conditions for the accumulation of sediment, but indirectly contaminate the water circulation in all the neighboring pipes. Obviously a ready remedy for this part of the difficulty is the periodical and systematic cleansing of the dead ends by what is called the "blowing-off" process, whereby all the offensive sediment is effectually washed out through the various hydrant vents.

Although such measures produced good results in a way, the supply from the house faucets was still more or less turbid, bad smelling, and of foul taste, forcing the consumers either to use filters, or to boil the water, or to drink bottled waters altogether.

The necessity for this form of filtration has naturally turned public attention to the advisability of adopting it on the larger scale as applied to the entire supply. From every sanitary point of view it goes without saying that a large and comprehensive filtration system is now a public necessity. It is estimated that the cost for the work will approximate fifteen million of dollars. Large as this sum appears, it will certainly be a cheap investment for the present and future generations.

When such a plant is in effective operation, the question can be practically answered once and for all as to its necessity, utility, and far-reaching influences upon the general health of the public. There is abundant testimony to the effect that it is the only remedy for the constantly recurring befoulment of our water after every season of drought. It is comforting to know that the municipality has absolute control of our extensive water-sheds, and can guarantee so far as such is possible against all apparent dangers of typhoid infection of the river beds or reservoirs. Already the health board with commendable zeal is inspecting the entire area with the laudable intention of quieting public concern on that point, and of still further elim inating the future possibility of disease contamination.

Thus it would appear that with a proper filtration plant, every opportunity can be seized for making the water supply of New York what it ought to be, the best and purest of its kind the world over. It only remains now for the grand jury to add its powerful influence in the right direction.

THE ETIOLOGY OF ACUTE ARTICULAR RHEUMATISM.

ALTHOUGH much study has been devoted to the etiology of acute rheumatism, there is as yet a want of unanimity of opinion with regard to the ultimate causative factor. The disorder was formerly believed to be due to metabolic disturbances resulting in the presence of an excess of lactic acid in the blood, but with the advances in our knowledge of disease causation, coincident with the development of bacteriology, acute rheu matism has come to be looked upon as a specific infectious disease. A number of observers have isolated micro-organisms from the lesions and the tissues, but, as indicated, there are wide differences between their results. Thus, staphylococci, streptococci, diplococci, and bacilli have been severally found, and, with some of these, lesions have been excited in lower animals comparable to those of acute rheumatism. Now it is to be borne in mind that inflammation of one or of many joints may occur as a complication of numerous infectious processes, as, for instance, scarlet fever, smallpox, influenza, pyæmia, septicæmia, but such a condition represents merely a secondary or complicating or symptomatic manifestation of the primary disturbance, due to different etiological factors, and not, as acute articular rheumatism probably is, to a definite specific micro-organism yet unidentified. An analogy may here be made between the several varieties of angina due to any one of a number of micro-organisms, and that specific variety that we know as diphtheria and due to the diphtheria bacillus alone. With the object of reaching an independent conclusion in the matter, Poynton and Paine (*Lancet*, September 22 and 29, 1900) undertook an elaborate investigation, with the result of finding in eight suc-

cessive cases of acute rheumatism a diplococcus growing in liquid media in streptococcal chains. The organism did not thrive upon ordinary agar or upon serum-agar, and though it could be grown upon blood-agar, it appeared to grow best in a liquid medium of milk and bouillon rendered slightly acid with lactic acid. On three occasions the organism was isolated in pure culture, during life, from the blood of patients suffering from acute rheumatic pericarditis. It was obtained also after death from the pericardial fluid, from the heart-blood, from the valves, and from the throat of a rheumatic patient, as well as from a rheumatic nodule. In five of the eight cases the diplococcus was present in pure culture. Intravenous inoculation of rabbits with pericardial fluid and with pure cultures was followed by polyarthritis and endocardial and pericardial complications; and from the lesions, as well as from the kidneys and from the liver, diplococci were isolated. The micro-organisms were found also in the heart valves or pericardium in eight other cases of undoubted rheumatic fever, and in the pia mater and brain in a fatal case of chorea. The organisms are believed to be identical with those previously described by Triboulet and by Wassermann, but the opinion is expressed that while they are probably the cause of all cases of rheumatism that conform to the usual type of the disease, they cannot be claimed to be the only cause.

SEPARATE PRISON FOR CONSUMPTIVE CONVICTS.

Dr. W. H. Blake has been indefatigable in pleading the cause and untiring in his efforts to better the conditions of those unfortunate prisoners who are suffering from pulmonary tuberculosis and of those who are compelled to live in close association with them. Dr. Blake, who is physician on the board of inspectors of convicts for Alabama, is able to speak with authority on the subject, and, moreover, his views are in accord with those of all persons who have studied the hygiene of prisons. The statistics of deaths among convicts in the Alabama State prisons for the past twenty years show that for the first half of this period consumption caused 20.3 per cent. of the total mortality; for the last half it caused 42 per cent. In the penitentiaries of the different States, of the total deaths, the percentage caused by consumption reads thus: Mississippi, 20 per cent.; Arkansas, 20 per cent.; Florida, 30 per cent.; Ohio, 31 per cent.; Michigan, 33 per cent.; Alleghany County workhouse, Pa., 33⅓ per cent.; Virginia, 41 per cent.; Kentucky, 42 per cent.; Joliet, Ill., 70 per cent.; Huntsville penitentiary, Texas, 66 per cent.; Rusk penitentiary, Texas, 33 per cent.; Washington, 16 per cent.; Connecticut (1898), 60 per cent., and in 1897 every death that occurred in the penitentiary of Connecticut was caused by consumption. These are appalling figures and speak for themselves. It is now universally admitted that under certain conditions tuberculosis is a contagious disease. Living with and breathing the same air as a consumptive person is a method eminently calculated to spread the disease. Prison management in Alabama and in most if not all the other prisons mentioned is especially favorable to the propagation of consumption. In the Alabama convict institutions, for example, the inmates are not kept in separate cells, but from fifty to one hundred are confined together in a single large cell. Consumptive convicts, unless in an advanced stage of the disease, are shut in with the healthy convicts. The consequence is that the prison is, to a large extent, a death trap, and the mortality from consumption is increasing. Dr. Blake urges the cause of the convict in the following words: "There is only one remedy for this condition, and that is, to separate the consumptive convicts from the non-consumptive. We need something more than separate wards in the same building, or separate buildings on the same grounds. We need a separate camp for consumptive convicts, the further from the other prisons the better, in order to give the non-tuberculous prisoners the greatest possible immunity from this disease. With the organization of such a camp, and the exercise of painstaking care in detecting consumption in its early stages, and the prompt removal of such convicts to said camps; in doing this, we shall have accomplished all that our present knowledge of this disease points out as our duty in the premises. This would give the consumptive better treatment, and the well man a chance to remain well. In this matter, the duty of the State is plain. It has the right to deprive the offender of his liberty, but it has not the right to deprive him of his health." The foregoing is the weighty opinion of an expert as to the best means of improving the condition of the consumptive convict and of removing him when a probable source of infection to others. There is no need unduly to coddle prisoners, but at any rate they should be treated with ordinary humanity.

DOCTORS IN POLITICS.

The London *Practitioner*, referring to the paucity of medical men in the British parliament, makes some very apt remarks on the matter. The journal in question then quotes the following paragraphs from *St. Paul's Medical Journal*: "The Legislature committee of the Minnesota State Medical Society has undertaken the task of organizing the profession of the State into a body which will exert its influence politically upon the legislature. It is intended to exert this influence in such a manner that candidates for legislative honors shall fully understand the desires of the medical profession in the matter of legislation. . . . Perhaps no individual in a community can exert more political influence than the physician; the humblest among us daily meets and talks with many whom he can influence in a political way. The doctor who favors a certain candidate can sway scores of votes for his benefit, and equally he can sway those votes against an undesirable candidate. His power is practically unlimited in that direction." Commenting on the foregoing pronouncement of opinion, the writer in the *Practitioner* says: "Whatever may be the case in

the United States, the power of the doctor in political elections is very far from being unlimited in this country. Unquestionably he can often 'sway scores of votes,' but the majority of medical men would probably think it not politic and perhaps not strictly professional to be known as active canvassers. English statesmen have sometimes used physicians as intermediaries, and Lord Palmerston, in particular, found them very useful as collectors of political gossip. But it is not many members of the profession that have such opportunities of directly helping in the conduct of public affairs." There can be no doubt that both in Great Britain and this country the medical man is not the force in politics he is entitled to be by his numbers and education. However, it is the opinion of the *Practitioner* that the medical man in Great Britain is not likely to be anything but a negligible quantity. so far as ordering the affairs of the nation is concerned, in the near future, if ever. Here the position of the physician is somewhat different—he is not so bound down by the traditional precedents of his profession as in England, his numbers are proportionately greater, and the system of government is more in his favor. Undoubtedly the medical practitioner should have more to say in the ordering of public affairs than is at present the case, but at the same time whatever power he may gain should be strictly devoted to furthering the best interests of his profession and not as a means of feathering his own nest.

News of the Week.

Yellow Fever and Mosquitos. — According to a press despatch from Havana, Dr. Finlay is reported to have declared his belief that mosquitos are the only propagators of yellow fever, and that if Havana could be kept absolutely free from yellow fever for two or three months all the infected mosquitos would die, and then the only way the city could again become infected would be through the importation of a fresh case from another place. This is what appears to have occurred in Santiago, which has enjoyed a long period of immunity from its former scourge.

Plague Precautions in New Orleans.—The New York *Times* states that the Louisiana board of health has adopted some important changes in the rules governing coffee ships from plague-infested ports, and now uninfected vessels will be detained only five days, so far as the cargo is concerned, instead of fifteen as in the past. The vessels are to be disinfected in midstream, will anchor one hundred feet from shore at night, and forty-five feet from shore in the daytime. Metal funnels will be used on the hawsers attached to the shore, to prevent rats from leaving the ships, and a corps of men armed with shotguns will be stationed on shore and in skiffs to shoot any rodent that may attempt to get away. All dead rats are to be handled with rubber gloves and cremated. Long stage planks closely guarded will be used to get the cargo ashore.

The St. Louis Academy of Medical and Surgical Sciences.—At a recent meeting of this society the following officers were elected for the year 1901: *President*, Dr. Emory Lanphear; *Vice-presidents*, Drs. Carl Pesold and H. S. P. Lare; *Secretary*, Dr. O. L. Suggelt; *Treasurer*, Dr. G. M. Phillips; *Orator*, Dr. William Porter; *Librarian*, Dr. H. G. Wicks.

A Reception to Dr. S. Weir Mitchell was tendered at Philadelphia by the Penn Club on November 17th and was attended by many men distinguished in the professions and in commerce.

Sanitation Needed in Peking.—According to reports from Peking the sanitary condition there is becoming serious. Since the foreign occupation many Chinese have died of smallpox and other infectious diseases. Fearing that their funerals would be interfered with, they have kept most of the coffins containing their dead in their houses and courtyards. The question of removing garbage has become one of grave importance. As the natives are forbidden to deposit refuse in the streets there is now an enormous accumulation in their dwellings and yards. Smallpox, which is always prevalent, is much more malignant during the winter season, and the conditions are favorable for the rapid spread of epidemic disease among the foreign troops and the natives.

A Hospital for the Insane in Palestine.—A few years ago Mr. Theophilus Waldmeier, the founder and superintendent of the Friends' Mission on Mount Lebanon, directed his attention to the needs of the insane in the Holy Land, and, though advanced in years and identified with his particular mission field, consecrated the remainder of his life to an effort to establish a modern institution for their relief. He visited Europe and America, appealed to the charity of all nations, set forth plainly the facts which impelled him to take the step, and described the methods of treatment prevailing in the East, which were based upon the theory of demoniacal possession and were crude and cruel in the extreme. He wished to construct a modern cottage hospital, the blocks of which were to be provided by the different nations, and he asked of Great Britain an appropriation for the land and administration house, and of America, Germany, Switzerland, and Syria that they construct cottages for patients. The *American Journal of Insanity* now announces the success of Mr. Waldmeier's scheme, and the formal opening of the Lebanon Hospital for the Insane on August 6, 1900. The director, Dr. Wolff, is an accomplished specialist in nervous diseases, with a European education. The nursing staff consists of deacons and deaconesses from Europe and some young men and women from Brumana who will learn to nurse the insane. On the 16th of August there were nine men and five women under treatment.

Medical Inspection of Schools.—The physicians in Philadelphia engaged in the medical inspection of schools have decided to form a permanent organization and to petition the board of education and councils for compensation commensurate with the service

rendered. The inspections have thus far been tentative and experimental, and the services of the physicians have been rendered gratuitously. It is claimed that a large amount of the decrease of contagious diseases among children since the establishment of the system of daily medical examinations is due to this cause.

The Pan-American Medical Congress.—The following is a list of the American secretaries of section at the approaching Havana Congress: Medicine, Dr. Judson Daland, Philadelphia; therapeutics, Dr. Hobart A. Hare, Philadelphia; pædiatrics, Dr. I. N. Love, New York City; mental and nervous diseases, Dr. C. H. Hughes, St. Louis; medical pedagogy, Dr. Otis K. Newell, New York City; medical jurisprudence, Dr. H. A. West, Galveston, Tex.; dermatology and syphilography, Dr. A. Ravogli, Cincinnati; surgery, Dr. W. P. Nicolson, Atlanta, Ga.; gynæcology and abdominal surgery, Dr. H. P. Newman, Chicago; orthopædic surgery, Dr. John Ridlon, Chicago; railway surgery, Dr. Duncan Eve, Nashville, Tenn.; dental and buccal surgery, Dr. Eugene S. Talbot, Chicago; anatomy, Dr. Arthur D. Bevan, Chicago; physiology, Dr. A. P. Brubaker, Philadelphia; pathology, Dr. Hunter McAlpine, New York City; ophthalmology, Dr. John E. Weeks, New York City; laryngology and rhinology, Dr. G. H. Makuen, Philadelphia; otology, Dr. James T. McKernon, Philadelphia; obstetrics, Dr. Gustav E. Zinke, Cincinnati; general hygiene and demography, Dr. Alvah H. Doty, New York City; military medicine and hygiene, Major Jefferson Kean, U. S. A., Quesnados, Cuba; marine hygiene and quarantine, Dr. R. M. Woodward, U. S. M. H. S., Washington, D. C.

Yellow Fever in Havana.—On November 24th there were fifty-seven cases of yellow fever in Havana. During October there were seventy-four deaths from the disease. Of the entire number of reported cases sixty-two patients were Americans and two hundred and twenty-five Spanish immigrants. During ten months of the current year there have been twenty cases with six deaths among the troops, officers and men, stationed in Havana, as compared with twenty-six cases and seven deaths during the twelve months of 1899. Dr. W. C. Gorgas, U. S. A., chief sanitary officer of Havana, in a recent report to the adjutant-general says that during the past month many exaggerated reports of the yellow-fever situation have been published in the United States. . Out of a population of two hundred and forty-two thousand there have been since the first of January nine hundred and sixty-eight cases. The correspondent of the Associated Press published very widely the statement that every block in Havana had from one to seventeen cases. Major Gorgas says, however, that there are eight hundred and fifty-seven occupied blocks in the city, and of those three hundred and ninety-seven have had cases of yellow fever. Of the blocks which have had cases, two hundred and twenty-four had only one case, and only one or two blocks in the city approximated the numbers given by the correspondent referred to. In Havana there are sixteen thousand and four hundred and eighty houses, of which seven hundred and nine have had cases of yellow fever. Dr. Gorgas also calls attention to the good results of the present system of disinfection and isolation. In the five hundred and fifty-three houses in which one case occurred the sanitary methods employed were apparently successful and prevented a further spread of the disease.

A Woman Medical Graduate at Budapest.—The degree of doctor of medicine has recently been conferred on Fräulein Charlotte Steinberger by the University of Budapest. She is said to be the first woman to have been graduated with the degree of doctor of medicine in Hungary.

The Plague in South Africa.—A despatch from Cape Town, dated November 22d, announces that Sir Alfred Milner, the British high commissioner, has proclaimed that all the east coast ports of South Africa between the tenth and fortieth parallels are infected with the bubonic plague.

Nurses' Home for the Woman's Hospital.—At the forty-fifth annual meeting of the Woman's Hospital in the State of New York, held last week, it was announced that Mrs. Frederick F. Thompson, who recently resigned the office of treasurer, had offered to build a nurses' home in connection with the hospital, the home to cost between $100,000 and $150,000. The home will be built on the hospital grounds. This gift of Mrs. Thompson is in addition to another of $55,000 which she made in the early part of the year.

The Sanitary Condition of Chicago has very markedly improved since the opening of the drainage canal. For the first ten days of November the monthly death rate was .85 a thousand, which, turned into annual death-rate figures, is 10.56 a thousand. This is about the normal death rate for small towns and villages, and far below most city death rates. The low death rate is especially marked as regards typhoid fever. There were only eight deaths from that disease during the first two weeks of this month, which is at the rate of twenty-three a month, as against a November average of seventy a month during the years 1865 to 1899.

The Craig Colony Prize for Original Research in Epilepsy.—Dr. Frederick Peterson, president of the board of managers of the Craig Colony for Epileptics, at Sonyea, N. Y., offers a prize of $200 for the best original unpublished contribution to the pathology and treatment of epilepsy. Originality is the main condition. All manuscripts should be submitted in English. The prize is open to universal competition. Each essay must be accompanied by a sealed envelope containing the name and address of the author, and bearing upon the outside a motto or device which is to be inscribed also upon the essay. All papers received will be submitted to a committee, consisting of three members of the New York Neurological Society, and the award will be made upon its recommendation at the annual meeting of the board of managers of the Craig Colony, October 8, 1901.

Manuscripts should be sent to Dr. Frederick Peterson, 4 West 50th Street, New York City, on or before September 30, 1901. The successful essay becomes the property of the Craig Colony and will be published in its annual report. The committee has made no award for the years 1899 and 1900, for the reason that the essays submitted have failed to come up to the necessary standard of originality. The prize calls for original research as to the pathological anatomy, chemistry, symptomatology, etiology, nature, or treatment of epilepsy—in short, anything that will add to the sum of knowledge regarding this disease.

New Operating-Theatre at Bellevue.—A new operating-annex in connection with the surgical division, recently erected at Bellevue Hospital, was formally opened and dedicated last Saturday afternoon. The dedication exercises were conducted by the Rev. Dr. Huntington of Grace Church.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the navy for the week ending November 24, 1900. November 17th.—Passed Assistant Surgeon A. W. Dunbar detached from the *Monongahela* and ordered to the *Vermont* for temporary duty with the crew of the *Wisconsin* and then to naval hospital, Mare Island, Cal. November 22d.—Assistant Surgeon R. B. Williams appointed assistant surgeon from November 17, 1900. November 23d.—Assistant Surgeon J. T. Kennedy detached from the *Monocacy* and ordered to the Cavite naval station.

The Harvard Veterinary School is to be discontinued, it is said, because there are not enough students to pay the running expenses. For several years there have been successive annual deficits in the accounts of the veterinary department of the university; the corporation of Harvard has decided to receive no more students for that department, but the students already in the school will be given sufficient instruction to obtain their degrees.

No Free Treatment for Inebriates in Minnesota.—The legislature of Minnesota last year passed what was called the "jag-cure law," which provided that indigent inebriates, upon proper petition, might be treated at a private institution, and the expense would be borne by the county. The consent of the inebriate must have previously been obtained. The supreme court of the State has, however, decided that the law is unconstitutional, because it applies only to counties of over fifty thousand population, and is limited in its benefits to a certain number in each county—one per year to each ten thousand of population.

Against the Spitting Nuisance in St. Paul.—An ordinance was recently passed by both branches of the St. Paul city council and signed by the mayor, forbidding expectoration on the sidewalk under penalty of a fine of from $1 to $50, or imprisonment from one to sixty days. The duty of enforcing the law and arresting offenders against it devolves upon the police. The throwing of fruit skins and cigar stubs on the sidewalk is also forbidden. The ordinance was passed at the suggestion of the health commissioner. We trust it will be less contemptuously treated than is the health board's prohibition against spitting in street cars in New York.

Declining Birth Rate in France.—According to the official statistics recently published, there were 847,627 children born in France in 1899, which is nearly ten thousand below the already low average for the past decade. The number of marriages increased during the year, which perhaps presages an improvement in the birth rate for this year. There were 816,233 deaths reported in 1899.

Salutary Inconsistency.—A Denver Christian Science "healer" has published a statement to the effect that he always reports to the health department all cases of contagious disease that he meets in his practice. This must indeed be a wonderful science if its votaries can so read the thoughts of their clients that they can declare which are contagious and which not. The inconsistency is absurd, but nevertheless most salutary.

A Sanatorium at Mentone, Cal.—The Pacific Hospital at Los Angeles, Cal., will erect a large sanatorium at Mentone, San Bernandino County, Cal. It will consist of a two-story and attic building with forty bedrooms, a parlor, and dining, smoking, and reception rooms. There will also be a central pavilion, 100 by 150 feet in size. In addition to the main building there will be ten cottages for the use of patients, and a stone power house for electrical and steam plants. The buildings will be in the centre of a tract eleven hundred acres in extent.

New Medical School Buildings at Yale.—A block of ground on Cedar Street and Congress Avenue, New Haven, has been purchased by Yale University, and on it will be erected new and commodious buildings for the use of the medical department. The plans for the buildings are nearly completed and work will be begun in a few weeks. The entire Medical School will be removed to the new site in a year or two, and laboratory buildings, clinical buildings, and recitation rooms will all be clustered about it as a centre. The new school will be opposite the New Haven General Hospital.

Red Cross Celebrations.—It is announced that on the night of December 31st, the last of the year and the century, the American Red Cross Society will hold a number of watch meetings in this city to see the old century out and the new one in. There will be, according to the plans of Miss Clara Barton, thousands of other such meetings all over the country, arrangements for which are being made with various State and city authorities all over the land. The Red Cross plans to have its big meeting in this city in Madison Square Garden, where music will be furnished by a band of one hundred pieces and a chorus of one thousand voices.

Obituary Notes.—Dr. Samuel J. Pearsall died suddenly at his home in Saratoga on November 19th. He was seventy years of age, and was graduated in

medicine from the Hahnemann Medical College of Philadelphia in 1858.

Dr. Romaine J. Curtis died at Joliet, Ill., on November 20th, aged fifty-eight years. He was born in Huron County, Ohio, and studied at Hillsdale, Mich., and Buffalo. During the Civil War he became a cadet on a hospital boat. He was graduated from the Ohio Medical College in 1864. Later he was assistant surgeon on the United States flagship *Burnside*. He was said to have been one of the first railroad surgeons ever appointed in the United States. He was an attending surgeon to St. Joseph's Hospital in Joliet for ten years, and previously had been professor of pathology, bacteriology, and hygiene in the College of Physicians and Surgeons of Chicago.

Dr. Robert Acton died at the Presbyterian Hospital in this city on November 27th, at the age of thirty-two years. He was born at Kinsale, Ireland, and came to this country in 1891. He was a graduate of the Harvard Medical School, and was licensed at the Regents' examination in this State in 1899. He was visiting physician to the House of Correction on Blackwell's Island.

Dr. Frederick Cornell De Mund died at his home, in Brooklyn, on November 20th. He was seventy years old, and was born at Millstown, N. J. He was a graduate of Rutgers College and of the College of Physicians and Surgeons in this city in the class of 1855, and practised in New Utrecht from that time until his retirement in 1895. He was at one time health officer of the old town of New Utrecht.

Dr. Rufus P. Lincoln, of this city, died on November 27th from appendicitis, at the age of fifty-nine years. He was a graduate of the Harvard Medical School in the class of 1868. Early in his professional career he turned his attention particularly to the treatment of diseases of the throat, and speedily attained eminence in his chosen specialty.

Progress of Medical Science.

Journal of the American Medical Ass'n, Nov. 24, 1900.

Syphilis of the Upper Air Tract; Some Remarks on its Diagnosis and Treatment.—George L. Richards states that no case of primary syphilis of the upper air tract has been met in his private practice during the last four years. Secondary and tertiary manifestations are common, the areas most frequently involved being the pharynx and tonsillar region, the nose and larynx. The primary chancre is usually found on the tonsil and soft palate. The secondary manifestations occur in the upper air tract from three to nine months after the primary lesion, and are at first those of a simple catarrh with no particular diagnostic characteristics apart from the history, except that recovery is much slower than in ordinary simple inflammation of the region. The manifestations of the tertiary stage appear from three to fifty years after the primary lesion. All histories are in the main apt to be unreliable, and a diagnosis should never hang on the presence or absence of a satisfactory history, but should be made on the symptoms as positively as though a clear history were obtainable. It may be stated as practically an absolute rule that necrosis of the bony framework of the septum, in the absence of history pointing to phosphorus or some irritant poison as a cause, is of syphilitic origin. In the writer's experience the pharyngeal lesions have been the most troublesome, especially when occurring high enough up on the pharyngeal wall to result in adhesions between the pharynx and the pillars. An important diagnostic point is the almost total absence of pain in syphilis, whereas in carcinoma and tuberculosis, the diseases most likely to be confounded with syphilis at the tertiary stage, there is considerable pain, while the disturbance of nutrition and general constitutional dyscrasia are very marked. The writer believes in the combined treatment of mercury and potassium iodide for the third stage. The hereditary type is briefly considered at the close of this paper. The writer concludes by saying that in general syphilis is a disease to be treated with constitutional measures and not with the knife or curette.

Differential Diagnosis between Abdominal Typhoid and Appendicitis by Means of Iodine Reaction; Report of a Case.—Siegfried Weiss declares that the clinical value of the iodine reaction of the blood has an established place among the clinical methods of examination. In the case reported the following staining solution was used:

℞ Iodi sublim. 5
Potass. iodid. 1.5
Aquæ destil. 50.0
Muc. acaciæ. ..... ad consist. syruposam
M.

The patient was a girl nine and three-fourths years old. There seemed to be at first a type of influenza with a form of bronchitis, and intestinal symptoms—constipation, diarrhœa, and colicky pains. But when typhoid symptoms—splenic tumor, roseola, typhoid tongue and lips, the Widal reaction 1:40, and also the diazo reaction in the urine—appeared, then the diagnosis of abdominal typhoid was made. The fever was remitting and subfebrile in character, but typhoid symptoms in children are either atypical or irregular. The diagnosis was uncertain when the blood gave the iodine reaction and the presence of pus was shown. The tumor argued against the presence of typhoid, and the disappearance of the same was noticeable. The case proved to be one of suppurative local perityphlitic inflammation with adjacent peritonitis which subsided in the course of a few days. The iodine reaction disappeared with the disappearance of the tumor. The rapid convalescence which followed the tumor's disappearance, and the absence of the Widal reaction were against the diagnosis of typhoid, so that the iodine reaction was the important factor in establishing the diagnosis of suppurative perityphlitis as against abdominal typhoid.

The Value of Blood Examination for Diagnostic Purposes.—Julian Walter Brandeis first considers the diseases in which blood examination is essential to diagnosis. These he enumerates as: chlorosis, secondary anæmia, pernicious anæmia, leukæmia (both myelogenous and lymphatic), Hodgkin's disease, anæmia infantum, pseudo-leukæmia, malaria, relapsing-fever, and filaria sanguinis hominis. As characteristic of the blood of children the writer mentions the following points: A leucocytosis, polycythæmia, and increased percentage of hæmoglobin are characteristic of the blood of the new-born, but gradually disappear. Any influence retarding the child's development causes a leucocytosis, a large percentage of the corpuscles being lymphocytes, and the appearance of nucleated erythrocytes without necessarily the coexistence of an anæmia. Also, in the anæmias of infants and children the red cells are destroyed to a greater extent, and degenerative changes are more marked than in like cases in adults. Nucleated erythrocytes and myelocytes are more common than in anæmias of corresponding severity in adults. In certain cases the discovery of the etiological germ in the blood has rendered the diagnosis of the following diseases positive: Typhoid, tuberculosis, tetanus, ulcerative endocarditis, anthrax, grippe, glanders, septicæmia, pyæmia, and pneumonia. The writer then speaks of diseases in which blood examinations are an important aid to differential diagnosis and prognosis. For example, both in pneumonia and diphtheria the absence of leucocytosis in any but the mildest cases is a bad sign. Neusser is quoted as stating that in deciding whether a case of hysteria, neurosis, or psychosis would be benefited by castration, the presence of a eosinophilia suggests the affirmative.

The Treatment of Adenoid Vegetations of the Naso-Pharynx.—Otto T. Freer declares that it seems logical to conclude that, though a proportion of cases with adenoid vegetations of limited extent can be successfully operated on without general anæsthesia, nevertheless the operation is apt to be incomplete, haphazard, and imperfect, with a large element of lucky chance in its successful performance, and that consequently general anæsthesia is necessary to insure the thorough removal of the entire hypertrophy of the pharyngeal tonsil. It is important for the operation to be complete and thorough, for if any lymphoid tissue is left in the child it will not only not atrophy, but will often prove the nucleus of a new set of vegetations. Another reason for thoroughness is deafness, which is often caused by adenoids that produce no, or but little, obstruction to breathing. Some authorities believe that entrance of tuberculous infection through the lymphatic structures of the fauces and pharynx is the most frequent

source of pulmonary tuberculosis in later life. Freer believes that ether narcosis is to be preferred to any other. The most advantageous position for the patient is the one where he lies on his side and chest, close to the edge of the table, with the left arm placed behind the back. As to instruments used, the writer declares that a thorough operation with the Löwenberg and Ingals nasal-bone forceps removes the hypertrophied adenoid tissue for all time.

The Danger of Spinal Anæsthesia.—John V. Shoemaker, in reviewing this subject, states that he has seen a single injection give rise to alarming symptoms of respiratory failure. The procedure is likewise productive of marked pain. In order to avoid this effect, Bier and others have employed Schleich's infiltration anæsthesia as a preliminary measure. In some cases chill and fever have followed the injection. Severe and long-continued headache is not uncommon. Distressing nausea and vomiting have also been excited. Exceptionally staggering gait and sharp spinal pains were experienced on the day following the injection. In some patients profuse sweating, and in others marked debility have been noted. Numbness and tingling have occurred. In certain cases anæsthesia was not produced by the operation. It need not be mentioned that the operation should be undertaken with the most rigid aseptic precautions. Great caution in the use of this method should certainly be exercised.

Post-Operative Hemorrhage.—A. H. Cordier advises against the use of catgut for ligatures in abdominal work, preferring silk instead. Secondary hemorrhage, under the circumstances indicated, calls for the most rapid intervention possible, and is one of the most appalling accidents in the whole realm of surgery. He advocates the use of a drainage tube when bleeding is feared, for if the wound is closed up tight blood in an air-tight abdomen will not coagulate, and thus nature's great hæmostatic—a firm clot—is removed. He lays down the following propositions: (1) In diagnosticating post-operative hemorrhage, the operative history will aid much. (2) The symptoms of shock and those of hemorrhage are very similar. (3) In suspected cases the cutting of a single stitch in the incision will tell. (4) The surgery must be quick and decisive in these cases. (5) In cases in which bleeding is expected the tube should be used. (6) Large quantities of decinormal saline solution will save many patients. This should be used both *per rectum* and by injection into the veins. (7) Strychnine, belladonna, etc., will not control bleeding from a uterine or ovarian artery any better than from any other artery. (8) The surgeon should do what his surgical conscience tells him is right. Late researches in hæmatology make it appear that an internal concealed hemorrhage may be demonstrated by a careful blood count. This, it is stated, will show a decrease in the red cells and an increase in the white. Very similar symptoms accompany shock from various causes, such as internal hernia, etc., none of which produces a change in the red cells. If an operation was performed for the relief of an inflammatory process, this test would lose its value in part, as there would exist at the time of operating a leucocytosis. Saline infusions apparently increase the white cells at first.

Spasmodic Wry-Neck and its Treatment; Report of Two Cases with Recovery.—W. M. Leszynsky's patients were women, aged thirty-six and twenty-four years respectively. His plan of treatment was to inject atropine into the substance of the affected muscles, in combination with massage, and the methodical education of the muscles and their co-ordinating centres. He adds, that while the atropine treatment may prove exceedingly beneficial, nay, even curative in some cases, it is evidently unsatisfactory in many others, and should be considered only as an adjuvant to absolute rest and general management. He further states that it is universally recognized that the prognosis in these cases is always unfavorable, unless suitable treatment is adopted early in the course of the disease. Recovery essentially depends on the duration of the trouble and the persistency in the treatment. In old-standing cases that have existed for several years and have received only desultory treatment, or in those patients who have been unsuccessfully subjected to the customary routine methods of management, the prospect as to ultimate recovery is always very discouraging. Surgery should not be resorted to until the foregoing measures have been given a thorough trial.

The Etiology of Eczema with Reference to Recent Views as to its Parasitic Origin.—L. Duncan Bulkley enumerates the various causes which have been assigned for this common skin malady, and calls special attention to the views of Unna. Concerning seborrhœa he says that the scientific world has practically accepted it as an entity with a micro-organism as a probable etiological factor, though there is really no unanimity in regard to the character of the parasite. All that Bulkley admits as to the question of parasitic origin is that some of the organisms which exist abundantly on the skin do, when it has taken on disease, cease to be saprophytic and exercise more or less of a baneful influence in heightening the eruption.

The Pathology, Diagnosis, Special Prophylaxis, and Treatment of Tuberculosis of the Middle Ear.—By Seymour Oppenheimer.

Rational Physical Training for Women.—By G. A. Saxe.

Medical News, November 24, 1900.

The Operative Treatment of Ugly Ears.—John B. Roberts believes this subject particularly worthy of attention since the operative treatment for the correction of these conditions is free from risk and generally unaccompanied by confinement to bed or even absence from business pursuits. A lacerated or incised ear may be so carefully sutured that the shape of the organ may be well preserved even after considerable loss of structure. After the removal of tumors, or the occurrence of sloughing from burns or traumatism, it may sometimes be necessary to alter the shape or size of the uninjured ear to make it correspond with the injured member. If new tissue is demanded to replace that which has been lost, it may be transferred from the neck or cheek or transplanted from the hand, abdominal wall, or thigh. Orthopædic measures are applicable in some cases—pads, springs, or repeated use of collodion. Artificial ears of celluloid, papier maché, or platinum, properly tinted, may replace an absent member; or repeated plastic operations may suffice to restore some semblance of the original ear. Congenital nodules are to be excised as a rule. Very large ears may be reduced by excising a wedge-shaped piece or by taking a crescentic piece from the central part of the auricle and a horizontal strip outward from the centre of the convex margin of the crescent. Flaring ears are corrected by excising a vertical ellipse of skin and fascia from the posterior surface of the auricle and the adjacent part of the skull, and then cutting a vertical wedge-like strip from the exposed cartilaginous structure of the ear. The auricle is then sewed close to the skull. In lap ears the suggestion is made of stiffening the auricle by inserting a thin sheet of metal in the tissues, after which it might be bent to the normal shape of the organ.

The Nature Treatment of Tuberculosis.—R. O. Beard says that the study of the warfare waged between the human tissue cells and the bacillus tuberculosis teaches us the lesson that the task of the public sanitarian and the physician is largely one of prevention, and that cure—a secondary and short-lived possibility in the course of the disease—is best accomplished by extending the principles and methods of prevention to the assistance of the tissue cells. Only now are we learning that but two prime factors are essential to make localities favorable to the tuberculous patient—purity and dryness of atmosphere, in whatever latitude, at whatever altitude, on plain or mountain, in forest or on ranch. Consumptives should be isolated. Tuberculosis should be quarantined in our towns as effectively as yellow jack. As to the creation of the Minnesota park, the nature treatment of tuberculosis in this available region will repay the nation in men more than it can gain in timber by its destruction or in navigation by its saving. As nearly complete physiological rest as possible should be attained by the consumptive. Forced feeding is also an important element in treatment. The gradual increase of food is well endured even in advanced cases. The combination of all these measures should brighten the hope of control of this most destructive of the diseases of civilization.

The Boston Medical and Surgical Jour., Nov. 22, 1900.

Diphtheria Bacilli in Healthy Throats and Noses, with Report of Cases.—Francis P. Denny thus sums up the points which he specially wishes to emphasize. (1) Diph-

theria bacilli are seldom found in the throats of those who have not been exposed to diphtheria. (2) The bacilli are more frequently found in those who have been exposed, especially in those living under poor hygienic conditions or in institutions. (3) The conditions of institution life which favor the growth of the bacilli in healthy throats are the living together of a large number of persons in a limited air space. (4) Healthy individuals with virulent bacilli in their throats can spread the disease. They are just as dangerous as mild or convalescent cases of diphtheria, and ought, therefore, to be detected and isolated. (5) Cultures ought to be made among those who have been exposed to diphtheria—(*a*) by physicians among the members of a family who have been exposed, (*b*) by inspectors in the schools, (*c*) by health officers under any circumstances when they think the disease is being or may be spread by such individuals.

Some Observations on Renal Casts.—Walter E. Tobie says that since the centrifuge has come into more general use hyaline casts are found in many instances in which neither clinical history nor chemical examination would seem to point to their presence. Certainly there is no good reason for believing kidney disease to be increasing to the alarming extent that microscopical examination of urine might imply. Inasmuch as hyaline casts may be present for many years without symptoms pointing to their existence, these questions naturally suggest themselves: Is the mere presence of hyaline casts necessarily a grave omen? May not the disease be checked or even of itself cease to advance? May not hyaline casts be present in urine from kidneys whose excreting functions are practically normal?

Chronic Diffuse Interstitial Nephritis.—By Charles J. Enebuske.

A New Spinal Jacket.—By Edward A. Tracy.

Philadelphia Medical Journal, November 24, 1900.

Conveyance of Yellow-Fever Infection.—J. O. Cobb concludes his discussion of this subject by saying that, although he has the highest respect for Drs. Sternberg, Reed, and their assistants, still he cannot accept their mere negative positions as disproving the validity of the Sanarelli germ as the cause of yellow fever or as establishing the identity of this germ with Sternberg's bacillus X. These workers have not disproved the work of Wasdin and Geddings and others. The writer states that he is prepared to believe that mosquitos, and even bed-bugs and fleas, may convey this disease. He adds that it is discouraging to think that the mosquito may be the sole conveyor of the disease, for if it is we cannot expect to confine the disease to each infected house as has heretofore been attempted. Undoubtedly some infected mosquitos will certainly elude us and escape to other nearby houses. Yet this is not the practical experience of Marine-Hospital officers, for they have shut up the disease and prevented its spread under the most discouraging circumstances, even in the presence of mosquitos. In the midst of speculation the practical should be kept in mind, for it is well known that the disease can be confined to narrow limits by the *cordon sanitaire* when under the watchful care of trained quarantine officials.

The Occurrence of Malta Fever in Manila.—This report is made by Richard P. Strong and W. E. Musgrave. Four laboratory infections with the micrococcus melitensis are noted. One case in the Army medical laboratory, Manila, was inoculated through the conjunctiva, which is a comparatively rare portal of entry. The micro-organism of Malta fever was discovered by Bruce in 1887, since which time, cases have been reported in various localities. It is not confined to the Mediterranean basin. India, Hong Kong, Secunderabadin, the Deccan, Porto Rico, Corsica, England, and the Philippines are all reported as localities where this fever has been contracted. The attention of the physicians was first called to the existence of Malta fever in Manila in the post-mortem work. After being impressed from discoveries made in necropsies that Malta fever is not a very uncommon disease in Manila, a clinical search for the cases was begun, which has been rewarded by the discovery of several cases which give marked reaction with micrococcus melitensis in high dilutions. One of these cases had been diagnosed malarial fever, while two others were thought to be typhoid fever with relapse. The Widal reaction was absent, as were also the malarial parasites.

The Treatment of Sprains and of Some Fractures.—A. H. Tubby says that in a sprain numerous small vessels are ruptured at the moment of injury, and that there is an instantaneous out-pouring of a certain amount of blood and lymph, and that this effusion goes on for three or four hours. It is quite rational to apply cold during this period, and it is the best resource at our command. It constringes the vessels, lessens the amount of exudation, etc., so that the duration of symptoms is shortened and there is little liability of stiffness afterward. Furthermore, the amount of effusion may also be lessened by application of pressure and the placing of the joint in such a position that its potential cavity is lessened. During the period of quiescence the same line of treatment should be adopted, for there is some quiet effusion still going on. But when the second attack of pain ensues and it is becoming more severe, the application of cold is not of much value, since by this time the tissues are distended with blood and with lymph and effusion has now ceased to be poured out. The right thing to do is to apply heat, as hot applications not only diminish the pain but exercise a permanent effect upon the duration and the amount of swelling in this way. When the vessels which have been injured have recovered their tone, the application of hot water or of heat in other forms promotes absorption, so that the effused blood and lymph are as rapidly as possible taken up into the blood-vessels and lymph channels. During this time the joint should be kept at rest and pressure should be maintained on it by cotton-wool and a bandage, since well-directed pressure also assists absorption. When the amount of swelling is very considerable, hot applications and rest are not sufficient. The best thing is properly applied friction. In regard to fractures the writer lays down the following rule as to cases occurring about the elbow: "In all injuries about the elbow joint, except fracture of the olecranon, the forearm should be forcibly extended, then supinated, then acutely flexed—that is to say, the limb should be placed with the ball of the thumb of the affected limb resting against the neck on the opposite side. No splint is needed, and, indeed, is harmful, for the position can easily be secured by means of a sling passing round the neck and round the wrist." In separation of the lower epiphysis of the femur, the separated portion is usually dislocated forward and not backward, unlike the displacement which occurs in a transverse fracture of the lower end of the femur; the displacement is backward almost always in the latter case. Forward displacement of the lower epiphysis is accounted for by this circumstance—the epiphyseal line is directed from the front downward and backward so that the epiphysis more readily glides forward on to the shaft. In transverse fracture the line of fracture usually passes above the attachment of the gastrocnemius; hence the fragment is tilted backward. Reduction and retention in proper position can be accomplished by division of the tendo Achillis and forcible extension, or the limb may be put up with the heel touching the buttock, or the joint may be opened and the epiphysis fixed with a steel nickel-plated screw.

The Micro-Organisms of Vaccine Materials.—J. B. Buist records his experiments made in the course of the last fifteen years to determine the cause of opacity of vaccine lymph. All he is prepared to say is that this opacity was due to spores from unknown sources, of a yellow, brown, white, or orange color, even in specimens which had been kept fifteen years. These he regards as the active ingredient of the lymph. Some authorities have isolated these spores and inoculated them into calves, the virus from which would "take" in children, but direct inoculation of the spore products into the human being were failures.

Complete Inversion of the Uterus.—A case is reported by David Durran in a woman aged twenty-five years, in her third confinement. Improper methods of pressure on the abdomen were suspected as the exciting cause, but the midwife in attendance denied that such methods had been used. Symptoms and treatment were along the usual lines. The patient did well until the eleventh day, when delusions began to appear and ran on to puerperal mania, requiring institution treatment. Cure resulted after several months' stay in the asylum.

Unusual Conditions at Birth.—By A. J. Rice Oxley. Case I. was one of fracture of the clavicle with normal presentation. It occurred in a very rapid labor. Case II. was one of "congenital thickening of the sterno-mastoid." The case was one of forceps delivery, but the tumor was not a hæmatoma. Such swellings clear up of themselves.

Treatment of Acute Mucous Colitis and Dysenteric Colitis by Sulphate of Sodium.—Aviragnet divides acute colitis into two varieties: mucous and dysenteric. He outlines his treatment of these cases as follows. (1) Rest in bed; diet of water and milk. (2) The application of cataplasms or warm wet compresses for the abdominal pain. (3) Avoidance of large intestinal injections, which by producing distention cause great pain (sometimes intolerable), besides often increasing the inflammatory process. (4) Small laudanum injections to diminish the extreme frequency of the stools and the rectal tenesmus. This treatment is to be preferred to suppositories. (5) In order to combat the inflammation of the mucosa of the large intestine several measures have been suggested: (*a*) Introduction into the large intestine of medicinal substances; (*b*) administration of ipecac by the mouth; (*c*) purgatives. The writer much prefers to use sulphate of sodium or magnesium. With the employment of sulphate of sodium his results have been most remarkable. The drug has a marvellous action on the secretions of the large intestine; in a large dose it exaggerates them like all purgatives, but in a small dose it diminishes them and causes the disappearance of glairy and bloody hypersecretion. (The hæmostatic properties of sulphate of sodium have been well shown by the experiments of Reverdin, of Geneva.) The doses used are as follows: 10 to 15 gm. the first day, small doses for the following days; 5 gm. for example, in a child of twelve to fourteen years; 2 gm. in a child of two years. The writer believes that sodium sulphate given in small doses is a remedy of the first order in acute mucous or dysenteric colitis.—*Journal des Praticiens*, November 10, 1900.

Acute Intoxications.—Among other acute intoxications, Lemoine speaks of cocaine. The only cases known of acute intoxication by this drug are due to its surgical employment for producing local anæsthesia. The physician will surely be held responsible for these accidents, and so must know how to prevent and combat them. The first two signs of the intoxication are the vascular contraction which is shown by pallor of the face and peripheral tissues, and the nervous symptoms, such as delirium and incoherent speech. Arterial tension is raised, and convulsions both tonic and clonic soon appear. If death occurs it is caused by adynamia. In giving cocaine the patient should always assume the dorsal decubitus to prevent cerebral anæmia, and the dose should never pass the maximum of 10 cgm. At the first danger signal the patient should be immediately reversed. Amyl-nitrite inhalations are efficacious. Chloral hydrate, morphine, and bromide of potassium are good to combat the phenomena of cerebral excitation. If there is collapse, ether and caffeine hypodermically are indicated. The patient should be warmed by friction, hot applications, etc., to prevent the cooling of the body.—*Le Nord Médical*, November 1, 1900.

Therapeutic Value of Peroxide of Hydrogen.—Marcel Rifaux states that peroxide of hydrogen was discovered by Thérard in 1818. This substance is a colorless, odorless, liquid, having a piquant taste. It can be mixed with water in all proportions. Its oxygenizing power is considerable, for it gives up its oxygen with the greatest ease, which is the basis of its real antiseptic character. It is also a hæmostatic. Clinically it is of the greatest service in all fetid, suppurating wounds. Old chronic otorrhœa, for example, with fetid suppuration is rapidly deodorized by its use. It has been employed with some success for disinfecting the uterine and vaginal cavities. In epistaxis it is used as a hæmostatic. The writer concludes from the study of peroxide of hydrogen that it merits an important place in therapeutics, as it is non-toxic, inodorous, a powerful deodorizer, an antiseptic of value, and a hæmostatic of the first order.—*Lyons Médical*, November 4, 1900.

Prophylaxis of Tuberculosis.—E. Malvoz believes that various social measures ought to be taken to ameliorate the condition of consumptives. There should be opportunity afforded for education in hygiene; the physician should give public lectures on proper dwellings, food, and conditions suitable for workmen; an examination should be made of suspects. The earliest possible diagnosis of tuberculosis should be made, facilitated by bacteriological laboratories which should give gratuitous service. There should be associations to support the invalids, giving all the comforts which they ought to have. Physicians should receive both a clinical and bacteriological education which would enable them to make a very early diagnosis of this disease, and to understand its prophylaxis and treatment.—*La Presse Médicale*, November 7, 1900.

Münchener medicinische Wochenschrift, Nov. 6, 1900.

The Significance of Oliver's Sign in Aortic Aneurism and Thoracic Tumors.—F. Jessen reports two cases in which the tracheal tug, which is usually said to be absent in tumor and present in aneurism, gave positively misleading evidence. The first of these is that of a young girl, who, with no physical signs other than a left recurrent-nerve palsy and absence of the Oliver-Cardarelli symptom, succumbed to what appeared to be a deep-seated tracheal stenosis. Ulceration with subsequent cicatrization, due to syphilis or tuberculosis, was excluded from the history, the freedom from congestive conditions was against mediastinal tumor, and the absence of circulatory disturbances and of the tracheal tug was thought to rule out aneurism. The autopsy revealed a high degree of aortic endarteritis, together with an aneurism of the arch as large as a walnut and closely adherent to the trachea. The second case is that of a middle-aged woman, who presented a rather complex syndrome of pulmonary and other symptoms, among which the Oliver-Cardarelli sign was easily obtainable. Under urgent dyspnœa the patient died, and contrary to expectation was found to have had a mediastinal sarcoma and not an aneurism. In this instance the simulation of the aneurismal signs was due to the intimate relation of the new growth to trachea and aorta, both of which it partially surrounded. In the author's opinion, therefore, tracheal tug is not a diagnostic sign between aneurism and neoplasm, and simply indicates the presence in the thorax of an abnormal mass in close relationship to the aorta and trachea.

A Little Known Pupillary Reaction and its Therapeutic Value.—Hans Kirchner describes an apparently hitherto unnoticed ocular phenomenon which, although as yet too little studied to be of much practical value, may perhaps be developed into a useful diagnostic or therapeutic measure. The reaction which with few exceptions is found in all healthy individuals consists in a contraction of the pupil following voluntary closure of the lids, and is more marked the more energetically the muscular act is performed. The same effect may be even more strikingly produced by holding the eye open with the fingers while the effort is made to close it against resistance. Considerable difficulty may be experienced in eliciting the reaction owing to various interfering factors, such as the light reflex and Bell's phenomenon. It is interesting to note that a pupil which fails to react to light or accommodation may be brought to contract by this manœuvre, and, furthermore, that the reaction may be increased by practice.

The Occurrence of the Demodex Folliculorum in the Eyelid and its Relation to Conjunctivitis.—Karl Hunsche found this organism present in the eyelids of seventy-nine per cent. of the heterogeneous dead-house material investigated, and believes that in individuals over forty it is always to be found. Its occurrence with such frequency in the lids of those unaffected by any ocular disorder leads to the conclusion that it is unable to produce any lesion of the parts in question, and that especially the conjunctivitis acarica of Joers does not exist. The author's observations were conducted by epilation, with microscopical examination of the roots of the cilia, and by the preparation of sections of the lids, by which he was able to demonstrate the parasites *in situ* after hardening in formalin-alcohol and double staining with eosin-hæmatoxylon.

The Effect of Nutrient Enemata on Gastric Secretion.—Ludo Metzger, in order to settle the question as to whether the stomach is really at rest when feeding is done only by rectum, or whether gastric secretion goes on even under these conditions, has made a series of observations on men and animals. Briefly summed up his conclusions are that an enema of milk and eggs produces in the stomach only a small quantity of a faintly acid secretion which does not appear till one and a half hours after the injection. The bouillon-claret enema, however, is speedily followed by a highly acid secretion, which disappears within an hour after the feeding. Control experiments showed that this increased secretory activity was due to the presence of the claret.

Further Contributions to the Disinfection of the Hands.—By Schenk and Zaufall.

The Use of Reindeer Sinew as Suture and Ligature Material.—By A. Schiller.

Berliner klinische Wochenschrift, October 29, 1900.

Four Cases of Disturbance of Equilibrium.—Rieken reports four cases which came on suddenly during a period of damp weather during which influenza and rheumatism had been specially prevalent. The symptoms simulated in certain respects those of Ménière's disease, and are analyzed in

detail in the original article. The author admits that similar symptom groupings are seen under various circumstances, such as seasickness, vertigo from various stomach and uterine disorders, galvanization of the head, loud noises, alcoholic poisoning, etc. He thinks it very possible that toxic poisoning from a disordered gastro-enteric state is the underlying factor in some of these cases.

The Treatment of Callous, Resilient Stricture.—H. Lohnstein has devised an apparatus (figured in the original) for the purpose suggested by the title. The stricture is enlarged as much as possible by dilatation and then the special apparatus employed. The principle utilized is that of the Bottini electric knife, modified so as to form a urethrotome running in a proper cannula.

The Clinical Value of A. Schmidt's Methods of Testing Intestinal Functions.—By H. Phillippsohn.

Urinary Calculi.—By C. Posner.

American Journal of the Med. Sciences, November, 1900.

Biological Studies with Reference to Pathology.—Theo. Klingmann experimented with spirogyra threads by placing several in water in which was immersed a piece of copper foil. A control of plain water was used. In the copper water the first change noted in the spirogyra was the cessation of the protoplasmic streaming, the protoplasm becoming granular, while the division of the protoplasmic cylinder and the granular evolution in the protoplasm followed, together with retraction of the outer part of the tube and destruction of the chlorophyl bands. The same pathological conditions can be brought about by the action of various bacterial toxins and toxic blood-serum. Of one hundred and fifty cases about one-third of the patients were in perfect health, the other two-thirds being patients suffering from various disorders, such as epilepsy, neurasthenia, hysteria, mania, pyæmia, pneumonia, syphilis, tuberculosis, erysipelas, typhoid fever, diphtheria, measles and other infectious diseases, alcoholism, gout, and rheumatism. After the blood has been obtained it is dilated with 20 c.c. of water and thoroughly mixed; a few drops of the liquid are placed on a clean glass slide; a thread of spirogyra is put into this, and is observed under the microscope with about a No. 3 Leitz objective. The water which is used for diluting the blood is tested by placing a few threads of spirogyra in a glass dish containing some of the water, and is allowed to stand a short time. If the water is non-toxic, the specimen is not altered. The time in which the alteration takes place varies directly with the amount of toxin and the species of spirogyra. While changes in the spirogyra take place in the toxic blood solution, the blood of healthy individuals yields negative results.

The Rôle of the Alloxuric Bases in the Production of the Cardio-Vascular Changes of Nephritis.—Alfred Careno Croftan states that the alloxuric bases are, unlike uric acid and urea, very readily soluble in the tissue fluids, and are highly toxic. Their chief representatives are xanthin, hypoxanthin, adenin, and guanin. Xanthin and hypoxanthin are capable of producing the cardio-vascular changes in those forms of nephritis in which retention of excrementitious substances precedes the lesions of the heart and arteries. The author believes that the alloxuric bases are the primary factor in the causation of "gouty" kidney. In the "lead" form of interstitial nephritis, the toxic action of this metal is either the same as that of the alloxuric bases, or it can cause changes in the organism which lead to the formation of these bases. The same toxins may simultaneously produce both nephritis and arteriosclerosis (lead, gout, etc.). From his investigations the author concludes that the alloxuric bases have an important rôle in the production of the cardio-vascular changes observed in all forms of nephritis excepting the chronic indurative form sometimes seen as the result of senile arteriosclerosis.

The Blood in Neurasthenia.—Theodore H. Romeiser and Joseph Collins give a study of thirty-three cases, based on a differential leucocyte count, and give a detailed report of the conditions found. As regards the general features they record the following observations. Many cases showed a leucopenia—that is, a decreased ratio of leucocytes to erythrocytes, often quite marked. In connection with this they note that one of the therapeutic measures considered most efficient in the treatment of neurasthenia, namely, hydrotherapy, has the effect of removing this condition of the blood, for cold baths cause a physiological leucocytosis. Some patients, chiefly those well nourished and physically in perfect health so far as appearances went, showed a normal count; a few showed a slight leucocytosis, associated perhaps with a slight local inflammatory process otherwise unobserved, as would be the case had the patient an infection. Nearly all had a more or less marked oligochromia, often with many microcytes and a few poikilocytes. In one case a normoblast was observed. It is to be observed that in neurasthenia there is often a striking lack of correspondence between the intensity of the subjective symptomatology and that of the objective, and in general it may be stated that the hæmatological abnormalities both in kind and in degree correspond more with the objective than with the subjective clinical picture.

Multiplied Ossified Ecchondrosis and Exostosis of the Trachea and Larger Bronchi.—I. B. Diamond describes the gross and the microscopical findings in a case which involved the entire trachea and larger bronchi of a man aged forty-eight years. There were, on the one hand, seemingly true exostoses arising from the perichondrium, and on the other ecchondroses. He believes the bony rings to be ossified ecchondroses, and describes the process of their development. Very little can be said as to the clinical significance of these growths. They are rarely, if ever, recognized during life, except when situated at the upper portion of the trachea and when they grow to such size as to interfere with respiration. When situated in the larynx they are readily recognized and even successfully removed. It is remarkable that nearly all the patients have died from some pulmonary affection, as tuberculosis, abscess, or gangrene of the lungs. It would seem that as a result of the condition the respiratory tract is weakened against the invasion of microbes, especially since the epithelial cells are changed, even destroyed.

Examination of the Stomach Contents with Respect to Digestive Ferments and Digestive Products.—By Frederick A. McGrew.

The Journal of Tropical Medicine, October 15, 1900.

A Holiday in the Mosquito-Proof House in the Roman Campagna.—D. C. Rees visited Drs. Sambon and Low and gives an interesting account of his stay with them. The hut is situated in probably the most malarious spot in the whole Campagna, practically on the banks of one of the main canals which in September is literally swarming with Anopheles claviger. The days were spent in scientific work and in entertaining eminent scientists and other visitors. The resident party turned indoors before six o'clock, at which time the door was locked and no one allowed to enter. The Anopheles would appear outside as regularly as clockwork. They do not bite in the daytime. The windows were wide open all night, so that marsh air came in freely, but in spite of that, in spite of their being out constantly in the daytime, and getting soaked to the skin in the rainy season, no one of the party contracted malaria. The peasants of the Campagna and the inhabitants of Ostia were practically all down with it, and the picture of woe and misery.

A Case of Blackwater Fever in Trinidad.—R. C. Bennett reports a case of ordinary chronic intermittent malarial fever in which there was a sudden onset of urgent, dangerous hæmoglobinuric symptoms, in a region where blackwater fever had never been heard of before. No parasites were found in the blood. Many of the red cells were crenated and buckled. The patient had been taking much quinine. The author, however, does not believe that the condition was due to quinine, for he says that practical experience renders Koch's theory untenable. It would be more in keeping with the maximum amount of reasonable possibility to consider blackwater fever a "post-malarial condition"—occurring in cases that have been saturated with malaria—whose resisting-powers have been gradually lowered, and in whom an abnormal amount of malarial toxin has been accumulated and suddenly explodes, as it were, into acute hæmoglobinuric symptoms (rapid destruction of red blood corpuscles and loss of albumin).

Circumscribed Cutaneous Œdema.—A. B. Dalgetty describes an affection which is occasionally seen among tea-garden coolies in India. The patient comes to the dispensary complaining of stiffness and swelling in one hand, which has come on during the night. The dorsum of hand and wrist are found to be considerably swollen and to pit slightly on pressure, but there are no other symptoms. The patient cannot account for the condition. The author's patients were not noticeably anæmic, nor had they been suffering from malarial fever, nor from any constitutional

affection. The œdema disappears in from two to twenty days. Iodine ointment seems to aid absorption. The etiology of this affection is a complete puzzle.

Koumyss as a Therapeutic Agent—C. Fleuroff has during the past six years noted the following action of koumyss, or fermented mare's milk: (1) In anæmia, neurasthenia, and hysteria, amelioration of general condition and all symptoms; (2) in some cases of hepatic and renal colic, increase of the pain; (3) in diseases of heart and blood-vessels, negative results; (4) generalized tuberculosis, negative results; (5) in incipient and early phthisis, improvement of appetite, of digestive functions and of the general condition, increase of weight, diminution of cough, amount of sputum, fever, etc.; (6) treatment by koumyss should be long continued; (7) diseases in which it is contraindicated are: Atheroma of blood-vessels, heart diseases, abdominal plethora, rheumatism and gout, cerebral hyperæmia, the later stages of pulmonary phthisis, hæmoptysis, hepatic and renal colic.

Acquired Lesions of the Valves of the Pulmonary Artery.—M. Fisch reports a case of ulcerative endocarditis, localized on the valves of the pulmonary artery. The heart was increased in size, especially on the right. In the second left intercostal space, auscultation revealed systolic and diastolic murmurs of a rasping quality; at the apex there was merely a soft systolic murmur. The second aortic sound was slightly accentuated. The urine contained albumin. The temperature was high; a diaguosis was made of mitral insufficiency, and insufficiency and probably stenosis of the valves of the pulmonary artery. The author cites twelve cases of acquired lesions of the pulmonary artery found in literature, in addition to those mentioned by Barié in his work on insufficiency of the pulmonary artery.

The Pathogenesis of Acute Yellow Atrophy of the Liver.—N. T. Baïmakoff found in the liver of a patient who died from this disease diplococci which were situated among the red blood cells. They were stained blue by methylene blue, and were in groups of from five to ten, or twenty, or thirty. An aureole resembling a capsule was around them. They were found in every part of the organ. No success followed the attempt to cultivate diplococci taken from the blood during life, nor from blood taken after death from heart, liver, gall bladder, spleen, and kidneys. Diplococci may possibly be the cause of acute yellow atrophy, which is an infectious disease in which the liver shows more degeneration than do the other organs.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE WAR HOSPITALS COMMISSION—TYPHOID AT BLOEMFONTEIN—SIR WALTER FOSTER—NATIONAL HOSPITAL DISPUTE—THE BRADSHAW LECTURE ON URINARY PIGMENTS—SIR MICHAEL FOSTER ON EXPERIMENT—PLAGUE—DEATH OF PROFESSOR HUGHES.

London, November 9, 1900.

The South African hospital commission concluded the taking of evidence on Monday. The last witness examined was Mrs. Richard Chamberlain, as the reporters officially style her, or Mrs. Dick Chamberlain, as she prefers to be called. She is generally known as a woman who seeks a certain sort of notoriety, and on this occasion has succeeded in advertising herself beyond her usual circle. Some of the reporters say she threw about twenty thousand words at the commission in less than two hours. One of the more sprightly, as if despairing of finding the gist of her talk, gives himself up to describe her dress, her face, her eyes, her lips, and so on. This may, perhaps, gratify her vanity but cannot conduce to confidence in her statements. "Not so fast, please, my dear madam; not so fast," cried the president from time to time, but he was unheeded. When direct questions were put to her she exclaimed pettishly, "You are doing what every one did in South Africa, trying to make things as awkward as you can. You are behaving not as if you were judges, but as if you were counsel for defence of the army doctors." To this reckless impertinence the learned judge contented himself with saying: "You are quite mistaken, but we want you to understand that this is the end of the inquiry. We have taken an enormous quantity of evidence, and what we want is not opinions, but facts, madam; facts, facts, facts!" But what were facts to a woman with a grievance and determined to vent her spite on the whole department which failed to appreciate her proffered help—from the heartless director-general down to the dressers and orderlies? She repeated her former statements that the hospitals were filthy and had nothing for use, that plenty of fresh milk could be had if the doctors were not too lazy to get it, that many of the doctors were drunken, and the drunkards sent home with the care of the invalids on the voyage. Asked for names, she seemed non-plussed. "Write them down," said the judge, "we will treat them in confidence." At length she wrote down one and said she had forgotten another, but they could ask Lord Lansdowne: "He'll tell you, you know; and as to another, he is such a very, very nice little man, I don't like to tell his name—you must take my word for it." Many more unsupported assertions were made, but the president's appeal for facts, not opinions, remained disregarded.

At length the president asked: "Do you really mean to tell us that you consider your opinion better than that of the trained army medical men?" To this, with all the assurance of ignorance, if not impertinence, she replied: "Why, of course; if not, what is the use of my being here?" Could feminine logic go further?

What may be the report of the commission it is not worth while to conjecture, as it will probably not be delayed longer than is necessary to collate and digest the voluminous evidence. Meantime, some journals are drawing attention to the folly of the War Office in keeping the medical corps below the necessities of the army. The corps was estimated to supply fifty thousand men with medical aid, and by March it had to attend to five times as many. As late as June, Surgeon-General Hamilton wrote: "For years the condition of short-handedness of the R.A.M.C. both in officers and men has been urged upon the War Office with but little effect, the view of the authorities being limited to 'drugs and doctors,' the former to be purchased, the latter hired, when necessity arose."

With regard to the epidemic of typhoid at the front there is in a certain quarter a disposition to blame the government for declining Sir Walter Foster's offer to take charge of the sanitary arrangements. It is even asserted by some that the education of the army surgeon is imperfect as to sanitary matters. This is disingenuous. Netley has been in the van on these matters ever since the late Professor Parkes taught there. The Royal Army Medical Corps knows more about military hygiene and the requirements of camps than do civilian doctors. Sir W. Foster's work at the British Medical Association and in Parliament affords no guarantee that he knows much about sanitation, and if he had gone to Africa he would probably have had to read up the subject in Parkes and other Netley teachers. Events have happened which the most distinguished army surgeons foresaw as likely, and Sir W. Foster should be glad he had not the responsibility of meeting them.

The dispute at the National Hospital for the Paralyzed and Epileptic has advanced another stage, and a most important one. On Saturday *The Times* published a letter signed by fifty-eight prominent members of the profession, headed by Lord Lister. The signatures are those obtained by submitting the letter to the two seniors on the acting staff of every London hospital having over one hundred beds, and also to those gentlemen who have been presidents of royal colleges. In order to add weight with the general public the signatures were also obtained of those who hold court appointments or who are knights or baronets. The letter expresses a firm conviction that the demand of the staff for representation on the board is perfectly reasonable, and one which in other hospitals has conduced to harmonious working and efficient administration.

Will the board give way? If not, will the governors meet and dismiss them, or let the hospital fall from the position described by this document as "more than national?"

Dr. Archibald E. Garrod delivered the Bradshaw lecture at the Royal College of Physicians on Tuesday. He took for his subject "The Urinary Pigments in their Pathological Aspects." It would not be possible to consider in a lecture all the colored substances met with in the urine, or even all those which may have more claim to the name "urinary pigments." The lecturer accordingly attempted to deal only with a small group which may be met with, if only in traces, in the urine of persons in normal health; urochrome, urobilin, hæmatoporphyrin, and urocrythrin constitute such a group, and Dr. Garrod confined

his attention to them and gave as full an account of them as he could in the time at his disposal. The most abundant is urochrome, to which probably the yellow color of normal urine is due. Urobilin occurs only in small quantity in normal urine, and that in the form of chromogen. It does not influence the color, but in some morbid states it appears in much larger amounts, and to a great extent as formed pigment, when it has a distinct effect on the color and can be shown by the spectroscope without the addition of any reagent. Hæmatoporphyrin is found only in traces in normal urine, but is often increased in disease, though very rarely enough to affect the color. Uroerythrin is perhaps not a strictly normal constituent, but it may appear in merely trivial deviations from perfect health. It is often abundant in morbid urines, and is the coloring-matter of pink urate sediments.

Dr. Garrod put forward no extravagant estimate of the importance of his subject. Such as it possesses, he said, is derived from the light it throws upon processes which are at work in the body both in health and in disease, especially upon those which are concerned with the disposal of effete blood pigment. Yet there are cases in which examination of the urinary pigments may afford information of diagnostic value and which may not be easily obtained in other ways. He therefore claimed that their study is not merely of academic interest. With this claim he concluded a very able review of this branch of chemical pathology.

Sir Michael Foster distributed the prizes at St. George's Hospital on Tuesday, on which occasion he gave an address defending experiment, and urged that every touch of the surgeon, every counsel of the physician, was in its very nature an experiment. An element of uncertainty was always present, although sometimes it might be almost insignificant. The hospitals ought all to be provided with thoroughly equipped clinical laboratories.

The last plague patient in Glasgow has been discharged from the hospitals. No fresh cases have occurred for six weeks, and unless a recurrence takes place the city and port will be declared free of the disease on the 13th. The epidemic has extended over three months, the cases numbering twenty-eight, the deaths only eight. Altogether Glasgow is greatly to be congratulated. A fatal case is reported from Bremen, and elsewhere suspicious cases are under observation.

Another victim to South Africa from our ranks—Professor A. W. Hughes, who went out with the Welsh hospital, died on Saturday, aged thirty-eight years. He carried through his work at the hospital and returned, but developed typhoid on the voyage, and a fortnight after reaching home the end came. He had the chair of anatomy in Cardiff University College for about four years, and then took that at King's College on the resignation of Professor Curnow. Here he won golden opinions and became dean of the school. He seems to have inspired esteem and affection in all his positions, and most remarkably in South Africa, where all ranks who met him lament his loss.

MOSQUITOS AND YELLOW FEVER.

To the Editor of the Medical Record.

Sir: It is with mixed feelings—of deepest regret at the untimely and almost heroic death of Dr. Lazear, of admiration for Dr. Carroll's self-devotion to the cause of science, and of satisfaction, seeing that my own experiments are being repeated and confirmed—that I have just read the preliminary notes of the United States Yellow-Fever Commission.

I am not in a position to express an opinion as to the importance of the experiments therein described, but I do feel bound to rectify some erroneous statements in which I am personally concerned, specially with regard to an experiment which I had commenced several weeks before I was honored by the visit of Drs. Lazear and Carroll. I had in my possession a small bowl in which several generations of mosquitos had been bred, and upon the sides, a little above the level of the water, there were numerous ova laid in the peculiar manner which the Culex mosquito so often adopts, namely, forming a ring all around the bowl, above the water. It occurred to me that, if mosquitos developed from the eggs of a contaminated mother are capable themselves of transmitting yellow fever, it would be important to determine how long the dry ova might retain the faculty of hatching. I, therefore, emptied the bowl of all the water and live wrigglers which it contained, leaving only the ova which adhered to the sides of the bowl. After having allowed the ova and the sediment to dry in the open air, I placed the bowl inside of a small, shallow kettle, into which it fitted nicely, and by fastening the lid on the kettle made sure that no other ova would be deposited. This was done on the 29th of June, so that when the United States commission called on me the dry ova had been kept isolated over one month. Dr. Lazear having expressed a wish to obtain some of my mosquitos I spoke to him about the experiment which I had in progress, and proposed that he should undertake to bring it to a close. As the means of procuring a good supply of those insects, I would hand over to him the bowl enclosed in its kettle, he might pour into it some water (preferably rain-water) on reaching his laboratory, and would kindly let me know whether my experiment had succeeded. Dr. Lazear eagerly accepted my proposal and carried off with him the whole contrivance. That the experiment had given a positive result I subsequently heard from Dr. Agramonte, and the fact is confirmed in Dr. Read's preliminary notes, but (in consequence, no doubt, of Dr. Lazear's death) the conditions of the experiment are entirely distorted and its object is completely ignored.

There is another statement which I beg emphatically to contradict, viz., "that I have not, as yet, succeeded in reproducing a well-marked attack of yellow fever, attended with albumin and jaundice." I assert most distinctly that I obtained every one of those symptoms in my very first experiment with a contaminated mosquito in July, 1881, that the patient had also bleeding from the gums, and that during the four years which the patient subsequently spent in Havana he never had another attack of yellow fever. In my subsequent experiments the conditions were such that I was in honor bound not to run the risk of developing an attack which might endanger life.

Finally, I should like to know whether the entomologist who identified my mosquito as the "Culex fasciatus" had taken into consideration the very remarkable manner in which the "Culex mosquito" lays its ova; for unless both present that important peculiarity their identity must be considered very doubtful.

Charles Finlay, M.D.
110 Aguacate Street, Havana, November 7, 1900.

A RACE-TRACK HOSPITAL.

To the Editor of the Medical Record.

Sir: Having to-day witnessed what to me, and as far as I can learn to others, is an entirely new departure, I think it wise that I should make it known; hence the present letter.

While in no way a "racing man," I received a courteous invitation from Mr. Thomas Williams, the president of the Pacific Jockey Club, to visit the course. While there we were invited to visit the hospital. I must confess that I was somewhat surprised, and that I expected to find a dirty room, poorly equipped, and redolent with odors which one is accustomed to find about stables; in fact, the very existence of an hospital in connection with a race course was novel.

What I really did find astounded me—a clean modern operating-room with sterilizers, instruments, operating-table, and such apparatus as one would expect to have in a well-conducted cottage hospital; a ward with beds completely equipped; a dispensary well stocked with drugs, and a storeroom containing splints, crutches, and surgical dressings.

On inquiry I was informed that a regular surgeon is employed, whose duty is to be present during the racing and give his undivided attention to any one who might be injured or ill.

This goes to show that there are thoughtful and kindly men in all walks of life, and that a too ready tendency to condemn the owners of large corporations, on account of their lack of interest in the physical welfare of their employees, is liable to lead us into error.

During the past decade it has been my experience to have treated quite a considerable number of jockeys who had been seriously injured, and whose condition was made infinitely worse by crude and imperfect primary treatment, followed by poor and unskilful transportation over long distances. Had hospitals existed such as that described above, there would have been a great saving to life and limb, for primary treatment has all to do with the subsequent course of the case, as any one who has had an army experience, or a large surgical practice in civil life must know.

I trust that this letter may be read by your subscribers, who may in turn be able to suggest a similar innovation to the owners of like institutions throughout the country. Jockeys are mostly lads of tender years, and it is indeed a kindly act to provide for their care when injured in the fulfilment of their work.

I might add that this corporation not only looks after the physical welfare of its employees, but goes a step further and interests itself in their mental advancement, which is evidenced by a night school with a staff of instructors.

George Franklin Shiels, M.D., C.M., F.R.C.S.E., etc.,
Professor of Surgery, Medical Department, University of California; Surgeon, San Francisco Polyclinic.
San Francisco, November 9, 1900.

Society Reports.

SOUTHERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION.

Proceedings of the Thirteenth Annual Meeting, Held in Atlanta, Georgia, November 13, 14, and 15, 1900.

The association met in the ballroom of the Kimball Hotel, under the presidency of Dr. A. M. Cartledge, of Louisville, Ky.

Governor Candler, of Georgia, delivered an eloquent address of welcome, which was responded to by President Cartledge.

Medullary Narcosis.—Dr. W. L. Rodman, of Philadelphia, read a paper in which he discussed the points of most practical value in connection with this method of anæsthesia. Would it displace ether and chloroform in operations below the diaphragm? In answering this question the author said that no one, however optimistic he might be concerning this new method of producing analgesia, would think of abandoning ether and chloroform. These trusted agents would continue to enjoy the confidence of the profession, and the Corning method would be held in reserve for certain cases in which there was seemingly a clear contraindication to chloroform or ether. Medullary narcosis should be induced in subjects suffering from bronchial, pulmonary, and renal diseases; in patients affected with fatty or dilated heart and cardiac diseases in general. It might also be induced in old people in whom the shock of general anæsthesia was oftentimes great, and from its action in one case the author believed it to be safer than chloroform or ether in drunkards.

The place where the spinal canal was entered was of some importance. Tuffier, Murphy, Matas, and others, who had had the largest experience with the method, preferred the fourth lumbar space. In the opinion of the author any of the lumbar spaces could be punctured with safety. The fifth interspace between the last lumbar and the first sacral vertebra was in some respects the easiest route.

The author considered the primary dangers of simple puncture without injection. It had not been shown that secondary changes, either inflammatory or degenerative, had taken place in either membranes or cord, leading to chronic disease. Theoretically, one might fear some form of sclerosis. Simple puncture of the spinal cord, if aseptically done, was unlikely to be followed by serious changes in the cord or its membranes. If to simple puncture was added the injection of some chemical substance by which anæsthesia was produced, a new element of danger was undoubtedly incurred. Therefore the choice of a local anæsthetic became of paramount importance. Cocaine was difficult to sterilize, as it could not be boiled without impairing its anæsthetic properties. Raised to a temperature above 180° F., it was decomposed into ecgonin, and became comparatively inert. Some had found it practical to boil cocaine and then to introduce it into the spinal canal, without impairing its anæsthetic properties. By raising it to a temperature of 180° F., and repeating this twice, thrice, even six times, as recommended by Tuffier, it should be sterile, and therefore safe, and yet a dose of ℥xxx. of a two-per-cent. solution of cocaine was too large, in the judgment of the essayist. He recommended half of this amount. A small dose of a two-per-cent. solution was better than a larger one in greater dilution. He had reduced the number of minims of a two-per-cent. solution each time he had practised the method, and thus far he had not failed to obtain complete analgesia. In his first case he had injected ℥xviii., in the second ℥xv., and in a third ℥xiii., and hoped still further to reduce the amount to ℥x. We should aim to get complete anæsthesia with the smallest amount of the drug. The primary and secondary effects of the injection of cocaine into the spinal canal were those of a simple puncture exaggerated. Shock was increased; headache, restlessness, delirium, and other symptoms were necessarily more pronounced. The speaker referred to the method of injection, and to the length, size, shape, and composition of the needle. He recommended an irido-platinum needle. He described the technique of the method, which was similar in many respects to that outlined by Tuffier and others. He blindfolded the patient and filled the ears with cotton to avoid psychical pain.

Dr. Lewis S. McMurtry, of Louisville, predicted that medullary narcosis would not take the place of the established methods of anæsthesia, and said that its field of usefulness would be restricted to the class of cases outlined by the essayist.

Dr. Willis G. Macdonald, of Albany, mentioned the case of a man forty-two years of age, who had suffered from hemorrhoids and fissure of the rectum. The patient had always been a hard drinker. Granular and hyaline casts were found in the urine, as was a small amount of albumin. The patient likewise had a fatty, dilated heart. The speaker had injected ℥xviii. of a two-per-cent. solution of cocaine in the subdural space, and when he was about to begin the operation the patient had become cyanotic; a profuse, cold perspiration had begun, so that it had become necessary to give the patient gr. $\frac{1}{60}$ of strychnine, and gr. $\frac{1}{30}$ of nitroglycerin, when the respirations had run up to sixty or eighty. No pulse had been discernible at the wrist. The pupils had been dilated; the patient had become unconscious. More than two hours had elapsed before the speaker felt safe as to the condition of his patient. The man had suffered severely from headache and projectile vomiting during the entire afternoon, and had had two or three involuntary bowel movements. Two days later Dr. Macdonald had administered nitrous oxide and ether, and operated on the hemorrhoids. The patient recovered. During the summer, while on a visit to Europe, he had seen a similar experience in the practice of Professor Kocher.

Dr. A. M. Cartledge, of Louisville, said his experience was limited to eight cases in which he had used this method of anæsthesia, the results having been satisfactory. In two patients severe headache, which soon disappeared, had followed its use. Analgesia was complete in all cases. In one case he had operated for the removal of pus tubes; in a second he had removed an enormous fibroid tumor of the uterus, and in a third a large intraligamentous cyst. Some of the patients had come off the table in much better condition than if chloroform or ether had been employed.

Dr. E. P. Mallett, of New York City, detailed a case of retroverted adherent uterus in the practice of Dr. Grandin, for which an abdominal section had been made. At first, much difficulty had been experienced in finding the subdural space or medullary canal, so that the patient complained of intense pain. It had been finally found, cerebrospinal fluid had escaped, and cocaine had been injected, the analgesia having been apparently complete in eighteen minutes. So much pain had been experienced while the operator was making the incision, that it had become necessary to administer a few whiffs of chloroform to complete the operation. He also detailed another case of posterior vaginal section for pelvic abscess. In this case the needle had been introduced more quickly and with better success; but slight vomiting as well as other

symptoms had occurred. The subsequent course of both patients had been uneventful.

Dr. Beverly Macmonagle, of San Francisco, spoke of two cases which he had seen in the practice of Dr. Barbat, of San Francisco, in which medullary narcosis had been used successfully. However, he had been told by both patients afterward, and by Dr. Barbat, that they had suffered a good deal from vomiting after they had been taken to their rooms, but had subsequently recovered without any marked incidents.

Dr. Seneca D. Powell, of New York City, did not think the time was ripe for this method to be presented to the profession at large. The results should be worked out by experienced hands. He pointed out the dangers of cocaine, referred to the susceptibility of some patients to the drug, and cited two cases that had occurred in his own practice in which he had used cocaine, saying that both patients had come very near dying from its effects.

Dr. J. W. Long, of Salisbury, N. C., referred to a discussion that took place before the Asheville meeting of the Mississippi Valley Medical Association, the consensus of opinion having been that the method was attended with danger except in the hands of experts.

Dr. Rodman, in closing the discussion, said he had used medullary narcosis on a man forty-five years of age, who had a bursa in the popliteal space, with marked kidney trouble. The result was satisfactory in every respect. The next case was one of advanced kidney trouble in which he had done a suprapubic cystotomy, with satisfactory result. He would use medullary narcosis in cases in which there were positive contraindications to ether or chloroform. The surgeon should always obtain the consent of the patient before using the method, on account of any medico-legal complications that might subsequently arise.

The Removal of Pelvic Inflammatory Masses by the Abdomen after Bisection of the Uterus.—A paper on this subject was read by Dr. Howard A. Kelly, of Baltimore. Recently the author had pointed out the great advantages which accrued from bisection of the myomatous uterus in an abdominal enucleation in certain complicated cases. In previous contributions he had described his method of enucleation by a continuous transverse incision from left to right, or from right to left. He now called attention to the great value of a somewhat similar procedure in certain cases of pelvic inflammatory diseases. The steps of the operation were these: If the uterus was buried out of view, the bladder was first separated from the rectum and the fundus found. Then, if there were any large abscesses, adherent cysts, or hæmatomata, they were evacuated by aspiration or by puncture. The rest of the abdominal cavity was then well packed off from the pelvis. The right and left cornua uteri were each seized by a pair of stout Museaux forceps and lifted up, the uterus was incised in the median line in an antero-posterior direction, and as the uterus was bisected its cornua were pulled up and drawn apart. With a third pair of forceps the uterus was grasped on one side of its cut surface, as far down in the angle as possible, including both anterior and posterior walls. The Museaux forceps of the same side was then released and used for grasping the corresponding point on the opposite cut surface, when the remaining Museaux forceps was removed. In this way two forceps were in constant use at the lowest point. He commonly applied them three or four times in all. As the uterus was pulled up and the halves became everted, it was bisected farther down into the cervix. If the operator preferred to do a panhysterectomy, the bisection was carried all the way down into the vagina. The uterine canal must be followed in the bisection, if necessary using a grooved director to keep it in view. The Museaux forceps were then made to grasp the uterus well down in the cervical portion. If it was to be a supravaginal amputation the cervix was bisected on one side. As soon as it was divided and the uterine and vaginal ends began to pull apart, the under surface of the uterine end was caught with a pair of forceps and pulled up, and the uterine vessels, which could then be plainly seen, were clamped or tied. As the uterus was pulled still farther up, the round ligament was exposed and clamped, then finally a clamp was applied between the cornu of the bisected uterus and the tubo-ovarian mass, and one-half of the uterus was removed. The opposite half of the uterus was also taken away in the same manner. The pelvis then contained nothing but rectum and bladder, with right and left tubo-ovarian masses plastered to the sides of the pelvis and the broad ligaments, affording abundant room for investigation of their attachments, as well as for deliberate and skilful dissection. The wide exposure of the cellular area over the inferior median and anterior surfaces of the masses offered the best possible avenue for beginning their detachment and enucleation. The operator would sometimes find, on completing the bisection of the uterus, that he could just as well take out each tube and ovary together with its corresponding half of the uterus, reserving for the still more difficult cases, or for a most difficult side, the separate enucleation of the tube and ovary after removal of the uterus. The operation just described was not recommended to a beginner in surgery. The surgeon who undertook it must be calm, deliberate, and must bear in mind at each step the anatomical relations of the structures. He had had abundant opportunity to demonstrate the practical value of this method of treatment in his clinic this year. The advantages of a bisection and enucleation of the uterus as a preliminary to a complete enucleation of uterine tubes and ovaries for pelvic inflammatory and other diseases by the abdominal route were briefly recapitulated: 1. Additional space for handling adherent adnexa was afforded by the removal of the uterus. 2. Great increase in facility for dealing with intestinal complications was secured. 3. There was better access by new avenues from below and in front to adherent lateral structures. 4. Elevation of structures to or above the pelvic brim, or even out into the abdomen, brought them within easy reach of manipulation and dissection. 5. Some advantage was gained in approaching both uterine vessels by cutting from the cervix out toward the broad ligament over approaching one of them in the continuous transverse incision. In general, the time of the operation was shortened; its steps were conducted with greater precision; surrounding structures were far less liable to be injured. In this way there were fewer troubles and sequelæ, and the mortality was lessened.

Dr. Willis G. Macdonald said his experience in bisection of the uterus, as an operative procedure, had been very largely associated with tumors of the uterus deeply situated in the pelvis, attended with great tension upon both broad ligaments. In dealing with fibroids of the uterus it had been his custom to follow the method improved by Dr. Kelly, and the only objection to the operation lay in a certain class of cases in which the tumor was deeply situated in the lower segment of the uterus, or extended to one side or the other in the broad ligament, or was associated with microcystic and adherent ovaries, so that when the operator lifted the tumor out of the abdomen to begin preliminary ligation on one side or the other, he caused considerable tension upon the broad ligament, and when the ligature was placed upon one or the other ovarian artery there was more or less danger of its giving way when the tension was released. He

had seen many cases in his own practice, and that of other surgeons, in which this accident had occurred.

Dr. J. Wesley Bovée, of Washington, D. C., said he had occasionally removed the body of the uterus previous to the removal of the appendages in pus cases, also in fibroid tumors of the uterus, but in some instances he had followed the method of Kelly, after he had read his paper before the Washington meeting of the association on the removal of fibroids of the uterus by going down on one side, as he had described it, and going up on the other. He had recently modified this plan in dealing with pus cases; namely, he cut off the tube and ovarian ligaments from the uterus on one side, clamped the round ligament, went down to the cervix, clamped the uterine artery, cut through the cervix and uterine artery on the other side, went up and removed the appendage on the other side with the uterus.

Dr. W. E. B. Davis, of Birmingham, Ala., expressed the opinion that the method outlined by Kelly would be of great assistance in the severe cases of inflammatory pelvic disease. The removal of the uterus for inflammatory disease had its origin in the difficulties which beset French surgeons in removing the appendages by the vaginal method, so that it became necessary for them to remove the uterus in order to have a route by which they could reach the adnexa. Dr. Kelly, therefore, had accomplished by operating from above what French surgeons had so frequently done through the vagina.

Dr. Beverly Macmonagle said he had seen Dr. Kelly operate on two cases by the method he had described, with very satisfactory results.

Dr. George J. Engelmann, of Boston, considered the method a step in advance, and said it was really amazing that no one had thought of doing this work by the abdomen before it had been done by the vaginal route.

Report of a Case of Osteofibroma of the Uterus.—Dr. George Ben Johnston, of Richmond, Va., narrated this case. The patient, Mrs. S——, aged thirty years, was the mother of three children, the youngest being three years old. About two years after the birth of the youngest child she had noticed an enlargement of the abdomen, and at times experienced difficulty in voiding her urine. She believed herself pregnant, but on account of the continuance of her menses and increasing difficulty of micturition, she consulted her physician, and an examination of the genital organs was made. This examination disclosed a tumor which filled the pelvic cavity, growing from the posterior wall of the uterus, and so displacing the uterus forward that it pressed upon the bladder. Six months later she missed her menstrual period, and by this time her size had greatly increased and her ability to void urine normally was almost lost. About the middle of March, 1900, after being all day upon her feet, a severe hemorrhage occurred, and the next day she passed a fœtus of six or eight weeks' development. Hemorrhage was promptly checked, but her size did not reduce and the pressure symptoms continued. He operated upon her April 10, 1900. Bimanual examination, made before the operation, revealed two tumors, one a large fibromyoma, situated posteriorly and to the right of the uterus; the other a small tumor, anterior and to the left. Complete hysterectomy was performed. The smaller tumor was found to be intramural and situated at the junction of the body and the neck. On liberation the macroscopical examination showed a tumor about the size of a small orange, and of firm consistence. Held between the thumb and fingers, it gave the sensation that was produced by pressing a hard-boiled egg, the shell of which had been broken. Plates, apparently of bone, surrounded the surface, and on opening it a substance resembling medullary tissue was found. This was unfortunately lost, so that no subsequent histological study of it could be made. Attached to the lower part of the osseous tumor was a small fleshy mass, which contained a body about an inch in length resembling a heart in shape. On opening the uterus a recent placental site was found near the uterine opening of the right Fallopian tube. Microscopical examination of the tumor developed the following characteristics: It was covered by a fibrous capsule, scattered through which were plates, rounded nodules, and irregular jagged masses, which, when decalcified, proved to be dense laminæ of bone, with their included bone cells. These bone cells were not so numerous as in normal bone, while the lamellæ were irregular in their arrangement, although showing a general tendency to lie parallel to frequent openings in the bony tissue. These openings were larger and more irregular in shape than the Haversian canals of normal compact bone, and were filled with a connective-tissue stroma supporting blood-vessels. The softer parts of the tumor were found to be composed of involuntary muscle fibres, arranged in groups and bundles, which were supported by loose connective tissue. Dense masses of fibrous tissue occurred throughout the tumor, independently of the muscular tissue. Microscopical examination of the tumor verified the diagnosis made macroscopically — osteofibroma. The patient recovered.

Dr. Howard A. Kelly said he would be loath to accept diagnoses that had been made twenty-five years ago in regard to tumors of this kind, when the difference between calcified tumors and teratomata was not clearly understood, and even pathology itself was in a vague condition. Of five hundred and sixty-one myomectomies, he had met with twenty-seven calcified myomata.

Dr. J. Wesley Bovée mentioned three cases that had come under his observation. In one the tumor was removed through the vagina, it being a submucous fibroid. The tumor pressed down the cervix, so that it required only slight slitting of the latter to remove it. Around the base of it he had found considerable bony structure in the body of the uterus near the fundus. Two other interesting cases were detailed.

Appendicitis in the Female.—A paper on this subject was presented by Dr. F. W. McRae, of Atlanta, Ga. At the outset, the author referred to an exhaustive article by Edebohls as to the relative frequency of appendicitis in the two sexes; also to the work of Einhorn, who had found in eighteen thousand successive autopsies perforating appendicitis in fifty-five per cent. of males, and fifty-seven per cent. of females. Robinson, in one hundred and twenty-eight autopsies, found evidences of past peritonitis in or about the appendix in sixty-eight per cent. of females, and fifty-six per cent. of male bodies. Clinically, Edebohls found that four per cent. of all women had appendicitis. On the contrary, Deaver believed that eighty per cent. of all cases occurred in males. Of fifteen hundred and seventy-seven cases of appendicitis collected from the annual reports of the city hospitals of Berlin, nine hundred and forty-nine were males, and six hundred and twenty-eight females. The speaker quoted eminent authorities to show the divergence of opinion as to the relative frequency of the disease in the male and in the female. In practically all of the cases that had come under his observation in females, mistakes in diagnosis had been made either by himself or by the attending physician. Almost all of the attacks had occurred at or about the menstrual term, and most of them had been diagnosticated "inflammation of the tube or ovary." In two cases of his own series the appendix and the right

tube and ovary were involved; in two others the appendicular trouble was complicated with dieased kidneys. Two patients suffered with recurrent appendicitis, and attacks of renal colic before or after operation for the removal of their appendices. He had records of forty-nine cases of appendicitis seen within the last sixteen months, twenty-nine of them being in males, and twenty in females. During this period he had operated on seventeen males and fourteen females. The author then detailed thirteen cases. Of this number Cases VIII. and XIII. were the most interesting, which we give herewith.

Case VIII.—Mrs. W. C. T——. First operation, October, 1899, for ruptured tubal pregnancy. Recovery with persistent fistula where drainage had been left. Second operation, May 10th. The fistulous tract was dissected out; a cyst of the broad ligament removed, together with a chronically inflamed and very much enlarged appendix, surrounded by dense adhesions and adherent to the broad-ligament cyst. The diagnosis at the time of the first operation was "acute appendicitis, with abscess," and the recovery from the first operation was tedious. The patient, who was profoundly septic at the time of the operation, recovered slowly, with characteristic septic temperature and pulse for several weeks. Whether appendicitis existed at this time or not, he was unable to say. Recovery from the second operation was tedious, but uneventful and complete.

Case XIII.—Miss B. C——, aged twenty-one years; seen in consultation with Dr. Summerfield. There was a history, extending over a period of about two years, of indefinite abdominal pain involving the whole right side from the liver to the pelvis. No definite diagnosis was made, and an exploratory operation was advised. Operation, September 7, 1899. The appendix was chronically inflamed, adhesions extending from the cæcum to the liver upward and down into the pelvis, involving the right tube and ovary. The right ovary was as large as a lemon, and the tube thickened and distended. The appendix, tube, and ovary were removed. The patient made a tedious recovery, developing a left saphenous phlebitis about ten days after the operation.

The cases were reported to emphasize the difficulties attending diagnosis. In several of them systematic treatment directed to the genitalia had been carried on without giving any benefit whatever, while the removal of the appendix effected a cure. In others, the ovaries and tubes had been removed, and still the symptoms persisted until relieved by appendectomy. The author was convinced that the great disparity in the statistics as to the relative frequency of appendicitis in the male and female was due, in a great measure, to mistakes in diagnosis. It was much more difficult to make a diagnosis of appendicitis in the female than it was in the male. Sufficient stress had not been laid upon the fact that appendicitis in women usually occurred at or about the menstrual period.

Dr. J. B. S. Holmes, of Atlanta, detailed three interesting cases of appendicitis in females, which illustrated forcibly the necessity of always examining the appendix when the abdomen of a woman was opened for any cause.

Dr. Hal C. Wyman, of Detroit, cited a case of extra-uterine pregnancy in which he removed a fœtus that had apparently died at about the end of the seventh month of pregnancy. The operation was done thirteen months after the appearance of the first symptoms of pregnancy. The appendix was found intimately blended with the fimbriæ of the right tube. The left tube had also suffered some disease, so that he doubted its perviousness. It was not removed because there was no particular indication for its removal. The right Fallopian tube, however, was involved with the appendix by dense inflammatory adhesions, and it occurred to him that in consequence of that blending the impregnated ovum had escaped. With this experience we might justly charge some of the cases of extra-uterine pregnancy possibly to adhesions between the fimbriæ and the appendix. The appendix was three and a half inches long; it had a number of scars; it was much hardened at its end, and at the point where union with the fimbriæ had occurred.

Dr. Howard A. Kelly stated that for four years past he had made it a rule at the Johns Hopkins Hospital to have the exact condition of the appendix stated on a slip. During this period he had removed one hundred and fifty appendices. Of this number sixty were involved in pelvic inflammatory disease. He had found the appendix adherent to myomata in twelve; adherent to ovarian tumors in nine. He had found carcinoma of the appendix secondary to ovarian carcinoma without any traceable macroscopical relation in one case, and primary carcinoma in one other case. He had found tuberculosis of the appendix secondary to tuberculosis in the tubes and ovaries in three cases; in the remainder of the cases calculi, cystic disease, and uncomplicated appendicitis. If, in an abdomen, opened for any pathological condition, the incision was sufficiently large, he would examine the appendix.

Dr. Lewis S. McMurtry mentioned a case in which he had enucleated an ovarian cyst in a woman of thirty years. She had had a typical acute perforative appendicitis, followed by septic symptoms, which was quite limited in the area of peritoneal involvement. When the abdomen was opened, it was found that the appendix, instead of perforating the general peritoneal cavity, pierced the ovarian cyst, in that manner limiting the infection to the ovarian cyst and saving the life of the patient.

Dr. Willis F. Westmoreland, of Atlanta, spoke of the practicability of stitching the kidney back through the same incision after the manner described by Dr. McRae in one of his cases.

Dr. William. P. Nicolson, of Atlanta, called attention to the coincidence of disease of the appendix and uterine adnexa, and cited cases in which symptoms for years had been ascribed to uterine or ovarian trouble, but operation had disclosed the fact that the appendix was solely at fault.

Dr. George Ben Johnston expressed the conviction that chronic appendicitis was quite as frequent in the female as in the male. He believed, however, that fewer cases of the fulminating form of the disease were seen in the female than in the male. He had observed numerous cases of chronic appendicitis associated with movable kidney in females, and it was sometimes difficult to determine which was the cause of distress for which the patient consulted a surgeon—the diseased appendix or movable kidney, or both. The coexistence of the two conditions was so frequent in his practice that oftentimes he kept patients under observation for days, perhaps weeks, to determine which was the more distressing condition.

Drainage in Abdominal Surgery.—The author of this paper, Dr. J. W. Long, of Salisbury, N. C., said that the chief purposes for which drainage was employed were to drain away existing septic material; to afford an exit for the sepsis when the operator feared he had possibly infected his patient; to provoke adhesions and thereby wall off weak spots from the remainder of the abdominal contents; to keep the peritoneal cavity free of blood and other fluids; to allow of a more certain knowledge of the conditions present in the abdomen. Gauze drains were sometimes employed as tampons to control hemorrhage.

These features of drainage were discussed in the order given. After referring to the work of Wegner, in 1877, and that of Muscatello, in 1895, and others, regarding the histology and physiology of the peritoneum, the author passed on to the consideration of objections to drainage, and these were enumerated as follows: 1. Dainage was deceptive. 2. Cases not drained did better. 3. Drainage was neither scientific nor workmanlike. The last statement was made with an apology and due deference to those distinguished gentlemen who drained most of their cases.

Dr. Manning Simons, of Charleston, S. C., agreed in the main with the observations of the essayist, but said there were some surgeons who would not admit that draining in suppurative cases was an evidence that something had been left which ought to have been removed, or that the surgeon had done something that he ought not to have done. He apprehended that there were many cases in which suppuration was not confined to the tubes, but had diffused itself more or less over the pelvic and abdominal cavities. The surgeon's conscience would scarcely, in such a case, prompt him to close up all avenues for the escape of reaccumulated fluid from the cavity. Drainage was applicable to such cases.

Dr. Howard A. Kelly believed that there was a tendency on part of the profession to drain entirely too many cases. Of his first one hundred cases, eleven years ago, he had drained in over eighty per cent. Of his last one hundred cases, he had drained in about one or two per cent. He would drain cases of localized sepsis, when he could not remove the entire septic area.

Dr. W. E. B. Davis referred to drainage in general septic peritonitis, and said it was impossible to lay down any fixed or definite plan of treatment because results were uniformly fatal. Reports in the past showed the percentage of recoveries to have been small. Much good could be accomplished by first using peroxide of hydrogen in the abdomen in this class of cases, and following it with infusion of decinormal salt solution, injecting, say, a quart under the skin every three hours. This accomplished even more than multiple drainage in cases of general septic peritonitis.

Dr. Beverly Macmonagle called attention to drainage in connection with surgery of the gall bladder and gall ducts. When the gall bladder was opened, it was absolutely essential to drain it. In all cases in which he had operated on the gall bladder, he had found it in such a condition that it was necessary to drain the gall bladder itself. In so doing it was almost impossible to drain it in such a way that a certain amount of fluid would not escape into the peritoneal cavity, hence the necessity of using a small drain of gauze in the peritoneal cavity itself.

Atresia of the Vagina.—Dr. George H. Noble, of Atlanta, described a flap operation for the relief of this condition, saying that he had operated successfully in several cases by the plan he had outlined.

Recent Technical Improvements in the Surgery of the Stomach for Carcinoma.—A paper on this subject was read by Dr. Willis G. Macdonald, of Albany, N. Y. Reference was made to the early history of operations for the relief of this disease. The technique employed by Billroth in his first pylorectomy was the technique of operations done by most surgeons for a number of years, with very slight modifications. This earlier operation presented many technical difficulties in its performance. The matter of the adjustment of the resected stomach and the duodenum at the completion of the operation was frequently defective. Secondary perforation at the line of suture with subsequent peritonitis had been a frequent cause of death associated with this earlier form of operation. Before giving a more accurate description of the preferable forms of surgical intervention in carcinoma of the stomach, the author considered the limitations of early and late exploratory abdominal section in the treatment of this condition.

Any one or a combination of the following symptoms was a sufficient indication for operation: 1. A chronic gastritis which was progressive in character under proper dietetic, medicinal, and physical treatment. 2. A loss of gastric motility. 3. Progressive diminution of gastric peristalsis. 4. A diminution of free hydrochloric acid, progressive in character. 5. Emaciation of the patient under forced diet. 6. Reduction of the hæmoglobin in the blood, progressive to sixty-five per cent. or under, and a moderate leucocytosis. The widest extirpation was demanded in carcinoma of the stomach.

The author called attention to the careful investigations of Cunec and Most with relation to the distributions of the lymphatics and lymph nodes as associated with carcinoma of the stomach. All surgery for carcinoma involved the removal, as far as was compatible with adjacent anatomical structures, of lymph nodes. In a complete pylorectomy, it was desirable to remove the lymphatics along both curvatures of the stomach, as well as those lying behind the pylorus. As a rule, the duodenum was not extensively involved in pyloric carcinoma, although a few observers had found infiltration of Brunner's glands in the upper portion of the duodenum. There was little justification for the total extirpation of the stomach in the majority of cases, and the probability of cure would not be greater than surgical resection. The old rule of cutting one centimetre beyond all evidences of carcinomatous infiltration was not wide enough. Personally, the author felt that the line of excision in the stomach should be at least three centimetres from the border of the last palpable infiltration, and in the duodenum at least two centimetres from the most dependent portion of the growth. The recently devised clamps of Kocher were presented for inspection, also diagrams showing their mode of application. By the application of these clamps to the stomach and duodenum, with a little care, all dangers of sepsis from the stomach and duodenum were avoided, and the rapidity with which a pylorus might be resected was greatly increased. Very little time was required to close the ends of the stomach and duodenum with a running catgut suture involving all the coats. This again was invaginated within the stomach and the calibre of the duodenum, and the stump buried by rows of Lembert sutures. The manner of performing the subsequent gastro-enterotomy lay largely with the preferences of the surgeon doing the operation. The speaker's earlier gastro-enterotomies had been done by the Woelfler method of attaching the jejunum to the anterior wall of the stomach. It appeared to him that the two fatal cases in which he applied that method were due to regurgitation of bile into the stomach and persistent vomiting following operation. Some two years ago he began employing von Hacker's method of attaching the jejunum to the posterior gastric wall with a reanastomosis between the duodenum and the jejunum. The results of this method of operation had been most satisfactory. During the past year he had employed it eight times, with seven recoveries. For the most part, the anastomosis between the jejunum and stomach had been made by the suture method, although a number of surgeons had been quite as successful in the employment of the Murphy button. For the secondary anastomosis the author had uniformly used a Murphy button of moderate size. The anastomosis by this method requires very little time for its performance and could be readily completed in five minutes When an operation had been carried out by this method

to its completion, the following advantages were claimed for it: 1. Freedom from contamination of the wound by stomach contents. 2. Accessibility of the neighboring lymphatic nodes for extirpation. 3. No subsequent danger from suture perforation. 4. Freedom from loss of blood. 5. The great saving of time required for the operation.

Lateral anastomosis could be readily accomplished by a variety of methods, including the button. Practical experience had shown through the more recent statistics of Mikulicz, Maydl, Kocher, and others that an operation of this form presented far less immediate dangers to the patient than did the older method of Billroth. The immediate mortality for the operation of pylorectomy was an interesting study. Ewald condemned the operation because of its great mortality, seventy-three per cent., and until 1888 the mortality had been somewhere in the neighborhood of sixty per cent. The mortality of Billroth was forty-five per cent., of Mikulicz thirty per cent., of Krönlein twenty-five per cent., of Maydl sixteen per cent., and of Kocher 8.7 per cent. Mayo Robson in a study of five hundred and seventy-two cases, collected from various sources, found an average mortality of 30.4 per cent. Guinard found that in one hundred and forty-eight cases of pylorectomy with end-to-end anastomosis, the deaths numbered fifty-six, or 37.8 per cent., and in sixty-four cases of pylorectomy with subsequent lateral anastomosis there were ten deaths, or 15.6 per cent. This showing had been equally favorable in the experience of others.

Menstrual Condition of the Average Girl in Average Health.—Dr. George J. Engelmann, of Boston, presented an interesting statistical paper on this subject, and the facts presented by him were culled from the records of forty-eight hundred and seventy-three cases from high and normal schools, colleges, and department stores. The girls were between fifteen and twenty-six years old, the majority between eighteen and twenty-two, in rather better than average health—in good health—and in numbers sufficient to admit of positive deductions as to what may be termed normal or average menstruation. In brief, the menstrual period proper was intensified by the increase of all vital energies, followed by a depression which appeared with the coming of the flow. Under ideal conditions, and in perfect health, the physiological status was such that this epoch, preceded by a day or two of heightened activity, was marked by a moderate lassitude, mental and physical, the flow persisting for from four to five days, and recurring at regular intervals of about twenty-eight days. It was a period of heightened susceptibility that quickly recorded any variation from the normal; excitement or exertion, or fatigue, mental or physical, were promptly reflected by variation in the function, and in our every-day life such disturbing elements constantly occurred, so that conditions actually existing varied greatly from this ideal. The average period of the average girl in average health presented very different features: Regularity in fifty per cent. of the cases only; recurrence every twenty-eight days in thirty per cent., varying most frequently from twenty-six to forty-two days, forty-five per cent. being over twenty-eight. The duration varied from two to seven days, average 4.6. From sixty-six to seventy per cent. suffered more or less, the number of sufferers varying, according to age and nature of occupation, between thirty and ninety per cent. Lessened ability for exertion, mental or physical, was admitted by sixty per cent. Some few were habitually incapacitated from work, and thirty per cent. occasionally. The function of the girl in good health, under modern conditions of life, was by no means an ideal one in the judgment of the essayist, and in fact the functional health of the American girl, the coming mother of American men, was far from what it should be by right of inheritance and surroundings. This fact physicians must recognize, and upon them and educators devolved the duty of study and correction of the evil.

Operation for the Treatment of Marked Prolapse of the Rectum in Women.—Dr. J. Wesley Bovée, of Washington, D. C., described an operation for the relief of this condition. In his case marked prolapse of the uterus was associated with hemorrhoids and great procidentia of the rectum in a woman to whom the uterine appendages were of little value. No simple operation would have relieved the rectal condition while the uterus was in such a state of prolapse, and vice versa. These conditions caused him to resort to the unique radical procedure which could be best described by narrating the following case:

Sister V——, thirty-five years of age, had been treated unsuccessfully a number of years for prolapse of the rectum, uterus, and hemorrhoids. When she came under the speaker's care she was suffering from large internal and external hemorrhoids, and a protruding roll of fully three inches of the rectum that was thickened and much discolored. The uterus was of normal size, with its cervix just behind the pubes, and the fundus very low posteriorly. A few days later, March 6, 1900, operation was done. The hemorrhoids were first removed, then the abdomen was opened by the usual subumbilical median-line incision. The left ovary was about three times its natural size, and largely consisted of numerous cysts. The appendages were removed and the uterus was firmly fixed to the abdominal wall by four interrupted, strong catgut sutures that passed through a considerable portion of the uterine fundus at the top, and the principal fascia of the abdominal wall on either side of the incision. The rectum was now drawn upward until it was fairly tense, and so held by an assistant until it was sutured to the cul-de-sac and posterior wall of the uterus up to the abominal wall. This was done by a running catgut suture. It completely divided the retro-uterine pelvic cavity into two equilateral ones.

Carbolic Acid in Surgery.—Dr. Seneca D. Powell, of New York City, read this paper. In 1894 he first became convinced that he could control the action of carbolic acid under all circumstances. At that time he used it in its full strength of ninety-five per cent. in an abscess cavity upon a patient suffering from suppurative appendicitis. Since then he had extended its use to all cases in which he had to fight disease due to microbic infection, and he was now prepared to assert its safety and reliability when properly brought in contact with an infected surface. He based his statements on the results of treatment of hundreds of cases which had come to his clinic at the Post-Graduate Hospital, New York. The essayist quoted Phelps, of New York, as saying that to him (Dr. Powell) the profession was indebted for one of the most useful discoveries ever made in surgery, namely, the antidotal effect of alcohol to carbolic acid. The speaker had used carbolic acid for years in the treatment of infections and bone diseases in various parts of the body. He recommended its use likewise for erysipelas and abscesses. During the past six years he had treated every phase of microbic disease with this agent, and as early as 1894 hip-joint cases were treated by him with pure carbolic acid and with a large glass drainage tube. Abscesses, wherever located, could be speedily treated by the injection of, or swabbing with, pure carbolic acid. The size of the abscess, or the amount of surface covered, was not a factor. Only thorough drainage and complete removal of the pyogenic membrane need be considered. The essayist dwelt upon its use in diseases in other parts of the body.

Early Excision for Dislocations not Reducible by Manipulation.—This subject was discussed by Dr. Willis F. Westmoreland, of Atlanta, who reported two cases. The first one was an arthrotomy, with excision of the head of the humerus, for old dislocation of the shoulder joint. Miss A. W——, white, aged twenty-four years. The patient was thrown from a buggy, the right shoulder and the elbow joint being injured. A physician saw the patient but made no diagnosis. On account of continued pain and lack of motion, she consulted a second physician, who recognized dislocation of the shoulder. An effort was made to reduce it, but he failed. Upon examination, the essayist found a subcoracoid dislocation of shoulder joint, and a badly treated fracture of the external condyle of the humerus. The patient was anæsthetized, and an unsuccessful attempt to reduce by Kocher's method was made. Any legitimate force completely failed even to move the head of the humerus. The patient was held for operation, which comprised a vertical incision, begun just below the acromion process, and carried along the inner aspect of the deltoid for about five inches. When the capsule was reached, it was split transversely; the head of the humerus was released from its attachments by dry dissection. The head of the bone was then turned out and excised close to the attachment of the capsule. The upper portion of the humerus was pushed up against the glenoid fossa, and the capsule shortened sufficiently to hold it there. In shortening the capsule all excess was inverted and helped to fill the cavity, leaving a very much smaller space to be filled in by adventitious tissue. In this case the slack of the long tendon of the biceps was excised, and the tendon united by mattress and coaptation sutures. The incision was closed except a small central opening for drainage. There was primary union, and the patient made an uneventful recovery. She was discharged with full movements.

Case II.—E. D——, male, white, aged twenty years. The shoulder had been dislocated two months before while boxing. Immediately after the injury a local physician had attempted reduction, but failed. Four days later the patient was anæsthetized, and Dr. Westmoreland made an unsuccessful attempt to reduce by Kocher's method. On the same day the same operation as previously described in Case I. was made, and the patient made an uneventful recovery.

A Plea for the Better Appreciation of the Limitations of Operative Work.—This was the title of the president's address, delivered by Dr. A. M. Cartledge, of Louisville. Every surgeon, he maintained, must be his own arbiter in deciding questions, and the judgment he displayed would depend upon his professional learning and wisdom. Methods of surgical diagnosis had undergone striking modifications within the past decade, and had influenced operative work. The older surgeon made his diagnosis of abdominal and pelvic lesions slowly; his skill at that time consisting largely of a delicate sense of touch, a trained eye to detect asymmetry, keen ears to differentiate sounds elicited by percussion, and methodical investigation of all symptoms both subjective and objective. The result was, his diagnosis having been made, he next carefully, and with abundant time before him, considered the advisability of operative intervention. It was as much a part of the knowledge of surgery to know its limitations, or what it could not do, as to be justly proud and ready to perform that which one had very good reasons to believe would be productive of relief and cure to the thousands of unfortunates who sought its aid. From every standpoint there was much to be gained by a better appreciation of operative limitations. A plea was entered for more careful diagnoses with an especial view to the detection of attending visceral disease, in short, for surgeons to try to become more expert prognosticians. There were two phases of surgical practice alone, the careful observance of which would reduce the mortality of surgical operations so low as to cause us to believe that exactness had almost been reached. He referred to greater care in the detection of kidney lesions and the institution of measures to correct this frequent cause of unfortunate operative terminations, and the still prevalent practice of operating upon hopeless cases of cancer. In reviewing the field of abdominal and pelvic surgery it would seem that surgical limitation was most often exceeded and mortality unnecessarily increased in operations for the following diseases: general septic peritonitis, extensive carcinoma of the ovaries, uterus, and intestine, and in operations upon the gall passages in long-continued and profoundly cholæmic patients without adequate preparation. He protested against the too frequent practice of operating in these affections. As to laparotomy in cases of general diffuse septic peritonitis, with irrigation and drainage, reports of such cases had appeared in literature from time to time, but the mortality up to the present time of such operations in exaggerated types of the disease was so great, in his opinion, as to make it an unwarranted procedure. He was strongly impressed with the belief that the successful cases reported had been cases of beginning general peritonitis, or of wide-extending, yet circumscribed, peritonitis. In closing, the author emphasized the importance of carefullfy preparing cholæmia patients before subjecting them to operation, with a view of lessening mortality. Another class of cases amenable to the same course of preliminary treatment were those of inefficient renal action.

Excision of the External Carotid Artery in Cases of Inoperable Malignant Diseases of the Face.—Dr. William P. Nicolson, of Atlanta, Ga., reported two cases upon which this operation had been recently done. The first case was one of sarcoma of the nose which had begun apparently as a polypus about eight months before. This was removed several times, but recurred promptly after each removal. When seen a few weeks before the operation, this had extended sufficiently to obstruct the nose completely and cause great pain by constant pressure. At the time of operation this had progressed in only a few weeks so that the growth pressing under the orbit had forced the right eye out of position, and there had been also an extension upon the forehead upon the left side. The patient suffered intense pain which required the constant use of morphine for its relief. The right common carotid was excised on October 3d, and the wound healed promptly. The enlargement upon the left side of the forehead broke down, and the large abscess was opened a few days after the operation. The pus from this, or the discharge from the nose, set up a violent ophthalmia, from which the patient suffered for a week or ten days. Two weeks from the day of the first operation the carotid upon the left side was removed, and very soon the symptoms improved in every respect, the patient was relieved of suffering, and the growth was not only checked, but it apparently began to recede, with the prospects of a material improvement in his condition. The second case was one of inoperable sarcoma of the upper jaw of three months' duration, and of very rapid growth. In this case the interval between the operations was longer than in the first, on account of the occurrence of a severe secondary hemorrhage on the seventh day, which was due to tying of the vessel too close to the bifurcation. The first operation in this case relieved the patient of all symptoms caused by the rapidly increasing pressure, and the growth apparently subsided materially. The second operation had not been per-

formed long enough to give much idea as to how much permanent decrease there would be in the tumor. In commenting upon the operation, it was claimed that in these cases the patient was simply doomed if nothing were done, and the operation performed appeared to be the only recourse that offered any hope of benefit. He had performed various operations upon the external carotid artery in cases of malignant diseases, having tied the vessel twenty-six times, four of these being cases of double ligation. The operation had not been accompanied by any mortality. Little could be accomplished by simply ligating even both carotids, because the circulation was re-established so rapidly that the nutrition could not be cut off with any degree of permanence. The operation of excision, as recommended by Dawbarn, seemed to be the only procedure that offered any hope, and while this would not perhaps produce much permanent effect, yet it seemed undoubtedly true that the lives of patients could be much prolonged and their sufferings greatly lessened. The operation was one of considerable magnitude, and dealt with structures of great importance anatomically, yet the results demonstrated that there was comparatively little danger in the performance of it.

Auto-Intoxication from Renal Insufficiency with or without Disease of the Kidneys.—By Dr. James T. Jelks, of Hot Springs, Ark. The author's attention was called to this subject several years ago by reading Bouchard on "Auto-intoxication," and later by papers from Etheridge, of Chicago, and L. Duncan Bulkley, of New York. For years he had made it a point to examine the urinary output for twenty-four hours of every patient who consulted him. This had been a revelation to him, and therapeutics based thereon had enabled him to accomplish what he described as marvellous results. Abundant evidence was adduced to show that as the result of faulty elimination by the kidneys, without the presence of disease in these organs, patients might have vertigo, contracted capillaries, cold skin, especially of the extremities, so-called sick headache, which was now recognized as uric-acid headache, melancholia, palpitation of the heart, interrupted heart beat, various forms of skin diseases, rheumatism, gout, hysteria, epilepsy, and even genuine insanity. Among the remedies used to correct this faulty elimination were squills, milk, rectal or hypodermic injections of decinormal saline solution, digitalis or its derivatives, sodium phosphate, sodium salicylate, Vichy water, etc. All of these were used in connection with baths, when it was possible to give them, and the patients were ordered to drink from one-half to one gallon of hot water daily. Twenty-five cases were detailed as having been treated along the lines mentioned, with the most gratifying results.

Dr. George S. Brown, of Birmingham, made (*a*) a supplementary report regarding a case of litholopaxy previously presented to the association, and (*b*) a supplementary report with reference to a case of vesico-rectal fistula.

Dr. James A. Goggans, of Alexander City, Ala., reported one case of strangulated femoral hernia in a woman forty years of age; three cases of extra-uterine pregnancy; one case of thoracotomy for empyema, and one case of ovarian cyst.

Some Life-Saving Measures in Obstetric Work.—By Dr. R. R. Kime, of Atlanta. Leaving out of discussion instrumental deliveries, Cæsarean section, symphyseotomy, etc., the author considered the most important life-saving measures to be saline infusions, medicinal remedies, orrhotherapy, hydrotherapy, and drainage. All of these topics were taken up and discussed in consecutive order. In cases of placenta previa and post-partum hemorrhage saline infusions or intravenous injections were of prime importance, not only to save life, but to lessen susceptibility of infection and hasten recovery. The report of one or two cases would illustrate some of the points brought out in the paper.

Case I.—Mrs. L——, primipara; her husband had had gonorrhœa before marriage. The patient had vaginitis and cervicitis, which were relieved by local treatment. At the fourth month of pregnancy the essayist removed by a continuous strip a lot of warty growths surrounding the posterior three-fourths of the vaginal outlet. The labor was normal. No lacerations occurred. Twelve days after labor there were a slight elevation of pulse, some headache, and a temperature of 99° F. The next day the symptoms slightly increased. The third day the patient had two chills, and the temperature was nearly 105° F. The uterus was found large and containing half a pint or more of pus; he irrigated, inserted double uterine drainage, and administered the usual remedies. The drainage tube collapsed and bent at the cervix, obstructing drainage, hence there was but little improvement the first twenty-four hours. After this rapid improvement took place, the temperature reaching normal in a few days. The patient recovered with normal pelvic organs.

Case II.—Mrs. L——, aged twenty-one years; primipara. Miscarriage occurred at about the fourth or fifth month. Two physicians in charge tried to empty the uterus with instruments, causing great pain. Some four or five days afterward a third physician took charge and called the essayist in consultation. He found the patient in a markedly septic condition, with a temperature of 103°–104° F.: pulse, 120 to 140; abdomen distended, tender, tympanitic, with abundant pelvic exudate. The uterine wall and cervix were sloughing. He removed some débris from the uterine cavity with forceps (not the curette), irrigated, and instituted double drainage, giving the usual remedies. The patient's general condition improved. The uterus rapidly assumed a healthy condition, it being practically normal in a week. At this time a vaginal incision was made, and the abscess cavity drained. The patient made a good recovery, was stout and healthy at the present time, and complained only of some pain during menstruation.

Pseudo-Membranous Enteritis and its Relation to Abdominal Surgery.—Dr. Frank A. Glasgow, of St. Louis, Mo., was the author of this paper. He called attention to this very common disease, and urged physicians to study its relations to appendicitis.

Solid Ovarian Tumor.—Dr. John G. Earnest, of Atlanta, Ga., reported a case of solid tumor of the ovary. The patient, Miss M——, aged thirty-two years, unmarried, was seen June 24, 1900. She was a very small woman with a narrow pelvis, and had been gradually losing flesh for several months, until she had become greatly emaciated. For months the patient had had fever every day. There was constant pain in the pelvis; she was very despondent, worn-out, and exhausted. She had a constant watery diarrhœa, which was occasionally interrupted by a few days' constipation, and accompanied by great abdominal distention. This condition, when occurring, was relieved with difficulty, requiring active purgatives and the free use of enemas. Nausea was a distressing factor. When the abdomen was inspected, a mass reaching above the umbilicus was observed. It stood out prominently in the median line, was symmetrical, smooth and hard. It was so firmly fixed that it could not be moved. The dark line down the centre of the abdomen was unusually pronounced. Examination by the vagina was somewhat hampered by an unruptured hymen, and tenderness due to the local peritonitis; but he found the cervix pointing forward, low down, and twice its normal size; the uterus was retroverted, firmly fixed, and apparently continuous with the superim-

posed tumor. Rectal examination disclosed that the uterus and tumor were parts of the same body. The fundus uteri could not be reached through the rectum. He believed it to be a uterine fibroid. The patient declined operation until she could go to her home and build up under the care of her family physician. This she did, returning August 1st. On August 3d, he opened the abodmen and evacuated a small amount of light yellow ascitic fluid. The abdominal peritoneum was mottled with dirty brown. The tumor showed the pearly lustre of an ovarian tumor. It had so grown that it seemed to be caught under the promontory of the sacrum, and was adherent to the pelvic wall. It was enucleated with some difficulty. The pedicle was from the right side, and comparatively small. The tumor, when removed, was found to be ovoid in its general outline, with an indentation corresponding to the promontory of the sacrum. It measured 20 cm. in length, and about 14 in breadth at the widest point. When cut open its appearance was very much like that of an ordinary uterine fibroid, and the tissue was quite dense. The cortex was united to the tumor by a thin layer of cellular tissue infiltrated with serum. No microscopical examination was made. At first it was supposed to be a sarcoma, but careful examination showed the fibres to be distinct and arranged in irregular whirls, as in uterine fibroids, and the tissues were quite as hard as those of any fibroid, and absolutely solid without a break. The recovery was uninterrupted.

Histogenesis of Ovarian Dermoids.—Dr. W. D. Haggard, Jr., of Nashville, Tenn., gave a verbal abstract of a paper on this subject. He stated that dermoid cystomata of the ovary differed essentially from dermoids in the orbit, pharynx, mediastinum, scrotum, coccyx, and elsewhere. The latter were unquestionably from inclusions or nipping off of the ectoderm in the development of the embryo, which was similar to the "healing in" of skin in wounds and the subsequent development of a dermoid growth. These structures all contained sebaceous material, hair, plates of bone, teeth, etc., and purely dermal derivates. Ovarian dermoids contained derivatives of all the mesoderm and entoderm as well, and hence some adequate explanation other than the inclusion of the skin-forming layer must be forthcoming. All sorts of curious theories had been successively advanced. The virginal pregnancy idea was succeeded by one which ascribed the origin of these growths to prolonged ungratified sexual desire on the part of the woman. A man who jested at his wife during travail was afflicted with a pregnancy (dermoid) of the thigh. Dermoids of the ovary, however, were akin to the teratomata, and it was to the ovum itself that we must look for a solution of the vexed problem of their etiology. Wilms was the first to claim the ovulogenous origin of these growths. Some pathological activity on the part of the ovum in the Graafian follicle was responsible. Bland Sutton found a dermoid of the ovary in a mare when the growth was undoubtedly in the ovum suspended in a large cystic Graafian follicle. Similar cases have been reported in women. Kraemer had recently gone over the entire field and amassed an amazing amount of material that went far to settle the question, and prove that ovarian dermoids contained products of all the blastodermic tissues; that they could not spring from an evolutional inclusion simply, as dermoids elsewhere undoubtedly did; that they were of ovulogenous origin, a sort of parthenogenesis. In evidence an attempt at formation of nearly all the organs of the body had been found in the lawless development of these benign growths—retinal pigment, more or less complete optical vesicles, a rudimentary pharynx, with an attempt at the formation of an œsophageal tube; the sympathetic nerves in the alimentary canal, and curiously enough a rudimentary uterus, with branching cells of the cervix and the glands of the fundus; mammæ (one case of which underwent carcinomatous development). An easily recognized heart provided with valves was found by Johnston; and many other more or less perfectly formed organs and tissues other than dermal had been reported by investigators too numerous to individualize. These data had, as remarked by Clark, dealt a telling, if not fatal blow to the inclusion theory of ovarian dermoid evolution. The researches of Kraemer and others seemed to establish convincingly the ovulogenous theory of their development.

The following papers were likewise read and discussed: "Removal of Cystic Gall Stones," by Dr. Howard A. Kelly, of Baltimore; "Osteo-Arthritis of the Spine," by Dr. Michael Hoke, of Atlanta; "Epi- and Hypospadias, with Special Reference to the Operative Treatment," by Dr. W. F. Parham, of New Orleans, and "Retroflexed Incarcerated Gravid Uterus," by William A. Quinn, of Henderson, Ky.

Much to the regret of the members, Dr. W. E. B. Davis resigned the secretaryship, owing to the pressure of other duties, after having served the association ably and efficiently from its organization to the present time. A resolution was offered and unanimously adopted, thanking Dr. Davis for his efficient services, tireless efforts, and faithful devotion to the interests of the association during a period of thirteen consecutive years.

Officers Elected for 1901.—*President*, Dr. Manning Simons, of Charleston, S. C.; *Vice-Presidents*, Drs. George H. Noble, of Atlanta, Ga., and L. C. Bosher, of Richmond, Va.; *Secretary*, Dr. W. D. Haggard, Jr., of Nashville, Tenn.; *Treasurer*, Dr. F. W. McRae, of Atlanta, Ga.

Richmond, Va., was selected as the place for holding the next annual meeting; time, third Tuesday in November, 1901.

Twenty-nine new members were elected at this meeting. After the installation of officers, and the adoption of resolutions of thanks, the association adjourned.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, November 6, 1900.

Frederick Peterson, M.D., President.

A Case of Paralysis Agitans without Tremor.—Dr. M. G. Schlapp presented this case. The chief features were the rigidity of the muscles, the expressionless face, and the position of the arms, body, and hands. The flexor muscles were more contracted than the extensors. There was no tendency to fall in any particular direction.

A Case of Paralysis of the Duchenne-Erb Type.—Dr. Schlapp also presented a man who, six weeks ago, had fallen from a bicycle, striking his shoulder. He had been unconscious for five hours. The case was interesting because the anterior pectoral muscles were affected. There was complete degeneration reaction of the pectorals, biceps, and the coraco-brachialis, and it was incomplete in the triceps and supinators. There was a peculiarly distributed area of anæsthesia showing involvement of the musculo-spiral and musculo-cutaneous nerves chiefly. The lower part of the pectoral muscle showed some slight response to the faradic current. The lesion evidently took in the fifth and sixth roots of the cervical plexus. As the anterior thoracic nerves were involved it was not a perfectly typical case.

Drs. C. L. Dana and M. Allen Starr said that they had each seen a similar case.

A Case for Diagnosis.—Dr. J. Fraenkel presented a man forty years of age, a tailor by occupation, who claimed to have been well up to one year and a half ago. There was no family history bearing on his condition, nor was there any history of any previous acute trouble. About eighteen months ago the man had been pushed roughly off a street car. On awakening the next morning at home he had been absolutely helpless, having been unable to move his upper or lower extremities. After six months he had been admitted to the Lebanon Hospital, but had left there, according to the history, unimproved. On coming under the speaker's observation, there had been noted at once the presence of an extensive eczema. On a second examination the shoulder joints had been found partially ankylosed, and the muscles surrounding them had appeared atrophic. There was also atrophy of the supraspinatus and infraspinatus, and slight atrophy of the serratus muscle. The electrical reactions were not changed. A thorough examination of his nervous system had proved absolutely negative. There were a peculiar atrophic condition of the skin and a condition of cyanosis on the peripheral parts. There was slight valvular disease of the heart. The diagnosis seemed to rest between rheumatism, a general trophoneurosis, and general syphilis.

Dr. B. Sachs said that he had examined this man previously and had been led to think of symmetrical muscular atrophies such as occurred after arthritic processes. It was not usual, however, to have them quite so symmetrical. The case did not seem to him to correspond to any of the dystrophies or any of the spinal forms of progressive muscular dystrophy. He had had a suspicion that the case might be one of leprosy.

Dr. M. Allen Starr said that, when travelling in Norway some years ago, he had seen a number of lepers, and had had his attention called to the existence of muscular atrophies in them. The peculiar appearance of the man's face had led him to think of leprosy without knowing Dr. Sachs' view on the case.

Dr. Fraenkel said that very careful inquiry had failed to elicit anything but the most positive statements that the man had been in perfect health up to the time of being thrown from the car. The man had come from the southern part of Russia. A dermatologist had seen the case and had been told that leprosy was suspected, but he had replied that the thickening of the face was due to the previous eczema.

Dr. Schlapp said that Bechteroff had described somewhat similar cases of "stiff back." There was a possibility of some of the roots being affected.

Dr. C. L. Dana thought this case was one of rheumatoid arthritis and the condition of the skin the result of an eczema.

Dr. F. Peterson thought it was an anomalous type of chronic rheumatoid arthritis. The fact that the muscles reacted normally would tend to confirm this belief. It was certainly not a spondylose rhizomyélique. This might, of course, be a case in which the spinal-cord symptoms were developed later.

Dr. B. Sachs presented the spinal column and the shoulders from a case of spondylose rhizomyélique. The heart also showed previous rheumatic disease.

Spasmodic Torticollis and its Treatment; Report of Two Cases with Recovery.—Dr. M. W. Leszynsky read a paper with this title. He said that wry-neck must be classified among the musculo-nervous disorders. The first case reported was that of Mrs. X——, thirty-six years of age, seen by him in 1895. About seven years ago she had suffered from pain and stiffness in the muscles of the back of the neck for several days. She had been greatly worried for a number of years by a protracted lawsuit. There was no family history of nervous disease. In February, 1895, after a fall on the ice, she had begun to suffer from nervous attacks, and in June she had first noticed a tendency of the head to turn toward the left. On examination, she appeared fairly nourished but anæmic. There was frequent and well-marked tonic spasm of the right sterno-mastoid muscle. Her eyes had been examined and found normal. Her general condition was that of neurasthenia of the lithæmic type. She was advised to rest in bed for three months, and was given the usual tonics. After two weeks atropine had been injected into the affected muscles, the daily dose being increased slowly up to gr. $\frac{1}{30}$. At this time the symptoms of atropine poisoning had been so severe that it was discontinued. For a few days after this the spasm of the muscles was decidedly worse. The convulsive attacks lasted about twenty minutes, were very violent, and were associated with marked impairment of respiration. Under the use of morphine and potassium bromide the paroxysms had gradually subsided in the course of two weeks. Subsequently various remedies had been employed, but without benefit. The urine was always acid and of high specific gravity. After four months there had been considerable improvement in her general condition but not in the spasm of the muscles. The rest treatment had been continued for some time longer under the advice of the late Dr. E. C. Seguin, but she had finally rebelled and had gone home. Some months later a brace had been applied, and this had gradually controlled the convulsive movements. The brace had then been discarded, but some tonic spasm in the muscles had still continued. Although there had been no return of the clonic spasm, there was still slight occasional tonic spasm of the upper segment of the trapezius muscle. This case pointed to a strong hysterical element, although the patient did not present the usual stigmata of this affection. There was undoubtedly also a lithæmic condition. The second case was that of a woman aged twenty-four years whom he had seen on October 24, 1897. At that time there had been a marked spasm which had existed for nearly eight months. She had suffered from migraine for a number of years, and there was no history of trauma. She was kept in bed and the usual rest-cure methods were employed for two months. The atropine injections had been used for about two weeks, and they had temporarily controlled the spasm. They had been discontinued after two weeks. She had made a complete recovery at the end of six months, and had remained well since that time. The speaker said that in 1884 he had recommended the use of atropine in this class of cases. Since then he had employed it in twelve cases, and had found that in many cases it was unsatisfactory, and he now believed it should be looked upon as simply an adjuvant to other measures. The prognosis depended upon the duration of the disease and the persistence of treatment. The principal therapeutic feature in every case should be the use of massage and the methodical education of the muscles and their co-ordinating centres. His attention had first been directed to this valuable method by Dr. Coggeshall, of Boston. It was a mistake to resort to surgical measures in the early stages of this disorder.

Dr. C. L. Dana said that in his experience if the wry-neck were pretty closely limited to the spinal accessory and sterno-mastoid an early resection would often check the disease and prove most useful. He quite agreed with the reader of the paper concerning the treatment of the older cases.

Acute Ataxia.—Dr. C. L. Dana read this paper, classifying acute ataxia as: (1) The acute bulbar and cerebellar ataxia; (2) acute spinal ataxia, and (3) acute peripheral ataxia due to multiple neuritis of the sensory type. He said that Ebstein had reported a case of acute ataxia with autopsy, and as patches of

sclerosis had been found the case had been looked upon as one of multiple sclerosis in an early stage. The peripheral type included the cases due to the sensory form of multiple neuritis. Up to recent times there had been no definite description of acute ataxia of spinal origin not due to tabes. In 1897 Dr. Strauss had, however, reported two cases occurring in men about thirty-four years of age without history of syphilis or other infection. The description seemed to the reader suggestive only of locomotor ataxia. The cases of acute ataxia first described by Leyden, and still referred to by him as acute bulbar ataxia, certainly had a strikingly characteristic clinical course, so that the name might have some clinical value. Special attention was called to five cases of non-tabetic spinal ataxia which were reported in the paper. The following is illustrative: A man aged sixty years on January 9, 1890, had begun to feel numbness in the feet, and in a few hours this had extended to the mid-dorsal region. He soon developed a tight sensation around the waist. Ten days later, on coming under observation, he had a staggering ataxic gait, and soon became tired. He could not stand with the eyes closed. He showed distinct loss of muscular sense, but no impairment of the functions of the rectum or bladder. The patient had gradually recovered, and was now well. In another case, that of a man seventy-six years of age, syphilitic infection had occurred one year previously. Just after recovering from an attack of iritis he had developed a type of ataxia like that described in the preceding case. In two other cases the disease had been in old people, but in neither of them had there been a history of syphilis. They both were victims of overwork, and both had presented symptoms of marked senility. It would seem that these cases were due to senile arterial changes, or due to syphilitic changes in the blood-vessels of the spinal cord, causing hemorrhages or blocking of the vessels, or both. It was possible that in old age the syphilitic virus might lead to attacks on the posterior rather than on the lateral columns, so that the type would be ataxic rather than of the spastic paraplegic type. All of his patients had recovered from the ataxia. The differential diagnosis must be made from an acute onset of a locomotor ataxia.

Dr. Joseph Collins said that his clinical experience had been somewhat different from that of Dr. Dana, so that he had been led to a very different conclusion regarding the etiology. Some of his cases had been in persons of about forty-four years of age without evidence of syphilitic infection. Sometimes there had been inability to walk in the course of a week. This had been associated with slight incontinence of urine at times, and with sexual impotence. In these cases there had been none of the cardinal symptoms of multiple sclerosis, and no evidence of cardiac or vascular degeneration. This was a type of case which he had been accustomed to call "acute ataxia." A second class of acute ataxia was acute bulbar ataxia. One of these was in a woman thirty-five years of age, who, about August 14th, had begun to complain of dizziness and blurred vision. Shortly afterward, while dancing, she had become ataxic, and then had lain in bed for a long time with marked ataxia and with slight anæsthesia of the face. The sense of position had been lost. Later, the symptoms of bulbar involvement—regurgitation through the nose and bulbar speech—had appeared. The cases of acute ataxia with which he was familiar clinically were those presenting similar features to the ones reported by Dr. Sanger Brown, of Chicago, recently, in *The American Journal of the Medical Sciences*. Dinkler had come to the conclusion that the lesion must be somewhere in the corona radiata or in the large basal ganglion.

Dr. S. Ely Jelliffe said that he had had under his observation for three years a gentleman thirty-six years of age, who had been infected with syphilis. He was a politician, and at the crisis of a campaign he had suddenly found himself unable to walk. On either side there had been ataxia confined to the lower limbs, and associated with some trouble of the bladder. He had been put on antisyphilitic treatment, and had been practically well in three weeks. He had remained well for a year, and then had had a sudden attack which had resulted in a typical spastic paraplegia. He had eventually died from this, and his spinal cord had exhibited the usual lesions of that affection. In the first attack there had seemed to be an acute ataxia due to involvement of the minor blood-vessels.

Dr. Schlapp reported the case of a man aged fifty years, an intemperate longshoreman. Three years ago he had developed ataxia and now had a disturbance of tactile and pain sense in the feet. Electrical reaction was diminished. The case looked to him like a neuro-tabes peripherica. The Romberg symptom was present. The knee jerks were slightly exaggerated. The case might perhaps be classed as an acute ataxia of the peripheral type

Dr. Fraenkel said that from the pathological standpoint the condition probably occurred quite frequently, and was often overlooked. He would like some points on the differential diagnosis between organic and functional conditions. The symptoms given by Dr. Dana were not sufficiently objective.

Dr. J. F. Terriberry commented upon the fact how these old people reported by Dr. Dana could have recovered so readily if the vascular system had been so damaged. For this reason he doubted if the vascular system had been especially at fault. Ataxia was a symptom rather than a disease, and the attempt to regard it as anything but a symptom was likely to lead one astray. He was in favor of considering the cases that ended in recovery late in life as of neuritic origin.

Dr. Dana said he had not met with the class of cases described by Dr. Collins. Dr. Brown's cases did not seem to be exactly cases of pure ataxia, and hence he had not referred to them. One must distinguish between an ordinary unilateral ataxia such as occurred from acute softening of the pons or medulla and the acute bulbar ataxia of Leyden, which is bilateral. It was a common experience to see old people with hemiplegia and hemorrhage recover in spite of the degenerated condition of the blood-vessels.

Medical Items.

Death Rebuking the Doctor.—Dr. X. B. Haynie writes that a Gallatin, Tenn., physician attended a funeral the other day, and after the burial services were over he with a number of people strolled among the graves of the colored population in a portion of the cemetery laid off for them. He noticed that the children's graves were decorated with almost anything and everything—a little chair, a broken top, and numberless toys that the departed pickaninny had possessed while living. Over one little grave the people lingered, and a variety of vials and boxes freshly labelled, "Take one teaspoonful every two hours till relieved. Take one powder every three hours till quiet," attracted their attention. What was the doctor's consternation to see his own name on every label!

Leprosy in Germany.—Some particulars are given in a recent number of the German Imperial Health Office Reports as to the prevalence of leprosy in the empire. On December 15, 1899, there were in Prus-

sia 22 undoubted cases of leprosy known to the authorities. Of these 16 belonged to the Memel district and 1 to the Rossel district; 1 was infected in Livonia, 2 in Brazil, 1 in Burmah, and 1 in the island of Penang. Of the 22 cases 10 were under treatment in their own homes and 11 in the leper house at Memel. In addition to the 16 recognized cases there were 4 doubtful cases in the Memel district. In Hamburg there were at the end of last year 10 cases known to the authorities. In 5 of these the patients, who were of German origin, were under treatment in private houses. The rest, who were foreigners, were in hospitals. In all of them the infection had been contracted abroad. In the middle of January, 1900, there was a case in the state of Mecklenburg-Schwerin. From the other federated states of the German empire no report has been received. The Memel district is the only native focus of leprosy in the German empire. Whenever leprosy has occurred elsewhere the infection has been contracted abroad. There appears to be some ground for suspicion that as regards Memel the total number of cases is not set forth in the official statistics.—*British Medical Journal.*

Typhoid from Shell-Fish.—The medical officer of health for Newington—one of the poorest and most crowded districts of London—has had several cases of typhoid or enteric fever reported to him, and having carefully inquired into them, believes the outbreak to be due to the eating of mussels and other shell-fish. He has accordingly issued notices cautioning the public against eating shell-fish, especially mussels, during the month of October.

Mosquitos and Malaria.—Laveran's discovery of the plasmodium of malaria was long ignored; then the credit was given to some one else. In the same way the mosquito theory has been claimed for Americans, Italians, and others; and, of course, for the noble savage, whose untutored mind seems not infrequently to see things hidden from the bespectacled eyes of science. In Koch's extraordinary reports from German New Guinea no mention is made of any other investigator; the subject is treated as if he were the Columbus of an unknown continent of knowledge. Koch has been a great scientific conqueror, and is fully entitled to his triumph. But the way in which he drags at his chariot wheels the discoveries of other men is ultra-Germanic in its insolence of self-assertion. In this particular field of research our German friends have done nothing at all. Laveran proved that malaria is a parasitic disease; Manson and Ross have shown how the parasite is conveyed to man. The Italians have worked out certain details of the problem by following the course indicated by the British workers. But the credit of the solution belongs to our countrymen.—*The Practitioner.*

Therapeutics and Hygiene of Obesity.—At the recent International Congress at Paris, Deschamps read a paper with the above title (*Le Bulletin Médical*, August 8, 1900). We should not content ourselves with a mere momentary reduction of weight, but should aim at securing physiological equilibrium between the ingesta and egesta. Diet, calorification, and muscular exercise are the most important elements to consider in the hygiene of obesity. The dietetic regimen should guarantee the patient sufficient food for all his needs, which includes the maintenance of all the gastro-intestinal functions. The regimen of choice is one in which vegetables predominate, and from which farinaceous and feculent articles need not be excluded. Water, pure or slightly alkaline, is the only drink to employ, and enough should be taken to quench the thirst. In certain cases it may be necessary to recommend an excess of water. Physiological calorification plays the chief rôle in reducing the weight of the corpulent. This is effected by prolonged bathing, the temperature of the water ranging from 33° to 36° C., and the duration one to two hours. The static-electric bath is an adjuvant of incontestable utility, as it also favors organic combustion. Muscular exercise cannot be imposed on the obese beyond a certain point. It is useful when regulated, but dangerous when it goes beyond the endurance of the individual. The temporary loss of weight obtained by its agency is more than offset by disorders of function which are set up.—*American Medical Review of Reviews.*

A Cure for Insomnia.—Dean Ramsey, the witty Scottish divine of the last century, used to relate an amusing tale about one of the earls of Lauderdale. His lordship was taken very ill, the worst symptom being insomnia in an aggravated form. His little son, hearing that recovery would be impossible without sleep, said: "Send for the preaching mon frae Livingston, for fayther aye sleeps when that minister is in the pulpit." The doctors considered that to act on the suggestion would be judicious; so the minister was immediately brought. He preached a sermon; sleep came on—and the earl recovered.

Athletics and Practical Physiology in Medical Schools.—Dr. Bayard Holmes (*The Plexus*, October) says: "Medical schools are now provided with lecture rooms, laboratories, libraries, and clinical conveniences, but with hardly an exception they are destitute of gymnasia, athletic fields, and lavatories. Before our education reaches that efficiency which the subject demands, these equipments must be added, and probably at the same time the feeding and social necessaries of the student will be improved and provided for, either from the student initiative or by the co-operation of the college and student."

Physicians' Beards.—According to an exchange, the Emperor of Germany says that all German physicians must cut off their beards. There are some physicians in the United States who would be glad to have beards to cut off; and there are others who would be seized with consternation should such an order go forth in this country, since their whiskers are their principal stock in trade, and the proper care of them seems to be their chief concern in life.—*The Stylus*, October.

Lord Lister and Vivisection.—The London *Pall Mall Gazette*, referring to the Huxley lecture recently delivered by Lord Lister, says that he can hardly be considered as a supporter by the anti-vivisectionists. In the course of the said lecture, the eminent founder of the system of antiseptic surgery gave details of certain experiments he had made on frogs, bats, and other animals. We have no doubt that, as Lord Lister himself put it, some people would consider that by these experiments, which he said caused no pain to the victims, he had "deserved a horsewhipping." Other people will probably agree with him that anything which contributes to the alleviation of human suffering is worth "the lives of a few frogs, or even of a rabbit." Considering the inestimable value of that antiseptic system, which, as Lord Lister said, "has been the labor of his life, and his contribution to the profession he loves," the price certainly does not seem excessive.

Diphtheria.—Is local treatment necessary? So far as danger of death from diphtheria infection is concerned it is not. But there is danger of other infections being implanted on the inflamed soil left by the diphtheritic process. It must be remembered, also,

that antitoxin does not destroy the diphtheria bacilli, and that they remain in the throat, nose, etc., for a variable period of time. That this period can be lessened by local treatment has been shown by the experience of Drs. McDaniel and Adaire at the State school at Owatonna. They sprayed or irrigated the throat and nose with a solution containing one-half of one per cent. of formalin, and succeeded in freeing the patients from bacilli in from one day to four weeks. Some of these patients had been showing the presence of bacilli continuously for several months.—Dr. J. P. Barber, *The Medical Dial*, October.

Masturbation and Albuminuria.—As regards the view that masturbation was the cause of albuminuria, which receives support from Moxon, Dickinson, and Clement Lucas, I have found that this form of sexual neurosis was present in a considerable number of my cases. While confirming their observations as to the existence of this neurosis, I cannot accept their conclusion that it is the cause of the albuminuria.—Dr. Sutherland, *The Clinical Journal*, October.

Chronic Gastritis.—The gastric mucous membrane has so much resisting-power that it practically ignores insult after insult offered it by dietetic errors, alcohol, and other irritants. A few years ago almost every symptom complex of the stomach was at once set down as due to subacute or chronic catarrhal gastritis, and even to-day the profession has not cut loose from this short-sighted, erroneous, and superficial habit. In point of fact, chronic inflammatory affections of the stomach are not very severe except as a result of grave organic disease located in the stomach or elsewhere. In many chronic diseases, as for instance the anæmias, the stomach is the organ that bears the brunt of the complaint of all the cells of the body, and it is not surprising that it should be chosen to cry out and rebel in the cause of the complaining cells depending upon it; but the point we wish to make is that gastritis exists in but a small proportion of these cases, and if the stomach and its contents are carefully studied there will be less often a hasty diagnosis of one or another form of gastritis.—Charlesont Stock.

Vaccine Infection of the Lips.—Alfred Jungmann says that accidental inoculations of vaccine virus are not so rare as is supposed. It is principally the nurses and mothers of vaccinated infants who are susceptible to this form of infection, owing to the many opportunities for direct contagion that their close association with their charges involves. Physicians are also liable to the accident, and a case is on record in which a splinter of glass flew from a vial of vaccine lymph while being uncorked, and struck the nose of the doctor holding it. He brushed it off unthinkingly, but the skin was slightly scratched and the customary lesion with its resultant scar developed. The case reported by the author is that of a wetnurse who infected a herpetic lesion on her lip from the vesicle on the arm of her newly vaccinated nursling. The lesion ran its usual course, though owing to the anatomical configuration of the parts a very extensive and temporarily disfiguring œdema developed. In addition to the unusual nature of the accident the case is interesting owing to the fact that the patient had already had variola, as was attested by the scars on her face, but the immunity acquired had apparently died out in the thirty years that had elapsed since the illness.—*Wiener klinische Rundschau*, September 23, 1900.

Women as Insurance Risks.—M. M. Danforth says that the investigation of statistics made by R. Hingston Fox showed that as a rule the female risks, if as carefully selected, would be even preferable to male applicants. As to the dangers incident to the child-bearing period, they are far less important as affecting the insurance risk than are those conditions of mental strain and worry incident to business, or the exactions of alcoholic excesses and dissipations so much more common in the male applicant. It has been stated that women are more apt than men to conceal important facts, but this the author denies, saying that not a few of the latest writers on the subject assert that women are more likely than men to give a truthful answer to vital questions. The so-called "moral hazard" of female insurance is a much overrated, if indeed not a purely imaginary, objection, unwarranted by the experience of insurance companies in general.—*The Medical Examiner and Practitioner*, October, 1900.

The Significance of Pain in Appendicitis.—E. H. Lee holds that in appendicitis, as well as in other abdominal lesions, the pain in the early stage of the disease is of a colicky nature, and due to an acute distention of the organ affected; the greater the distention, the greater the pain. Second, as soon as the acute constriction or distention has subsided or the obstruction has been relieved, these reflex colicky pains and nausea and vomiting cease, and the pains that are present after this time are of a steady character. They should be described more as a tenderness in the right iliac fossa, and are due to the circumscribed peritonitis. Third, this last-mentioned pain gradually subsides as the disease progresses toward its favorable termination, either by a perforation of the abscess into the bowel, or possibly by the absorption of the circumscribed inflammatory process.—*The Chicago Clinic*, October, 1900.

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended November 23, 1900:

		Cases.	Deaths.
Smallpox—United States.			
Maryland, Prince George Co.	November 9th to 14th	9	
Michigan, Detroit	November 10th to 17th	1	
Grand Rapids	November 10th to 17th	1	
Minnesota, Minneapolis	November 10th to 17th	3	
New Hampshire, Manchester	November 10th to 17th	10	
New York, New York	November 10th to 17th	1	
Ohio, Cleveland	November 10th to 17th	19	1
Tennessee, Memphis	November 10th to 17th	1	
Texas, Houston	October 31st to November 7th	6	
Utah, Salt Lake City	November 10th to 17th	20	
Virginia, Alexandria	November 18th	1	
Smallpox—Foreign.			
Austria, Prague	October 20th to 27th	8	
Brazil, Pernambuco	September 23d to 30th	..	15
England, London	October 27th to November 3d	1	
France, Paris	October 27th to November 3d	..	14
India, Calcutta	October 13th to 20th	..	6
Japan, Nagasaki	October 11th to 20th	1	
Mexico, Vera Cruz	November 3d to 10th	..	1
Russia, St. Petersburg	October 20th to 27th	3	3
Scotland, Glasgow	November 2d to 9th	31

TUBERCULOSIS OF THE EYE: ITS DIFFERENTIAL DIAGNOSIS, PATHOLOGY, AND TREATMENT.[1]

BY CHARLES STEDMAN BULL, A.M., M.D.,

NEW YORK.

IT may safely be said that all our actual knowledge of ocular tuberculosis dates from 1868, when Gradenigo published the first case, with confirmation of his diagnosis by microscopical examination. Tuberculous disease of any of the tissues of the eye is a rare disorder. The exact proportion of such cases to all lesions of the organ has never been accurately determined, but the proportion of cases of conjunctival tuberculosis, given by Eyre as 1 in 2,700, is probably much too large.

Tuberculosis of the eye is met with between the ages of five and thirty, though a few cases have been observed at a later period. It may invade any part of the organ, though the tendency of the disease is to attack in its progress the deeper structures primarily. Hence tuberculosis of the iris and chorioid is more frequently met with than the same disease in the conjunctiva and cornea. According to Baumgarten (1878), the only pathognomonic feature of tubercle, aside from the presence of the bacilli, is the tendency to caseation.

Tuberculosis of the Conjunctiva and Lids.—The eye may serve as the point of entrance of the primary infection, and generally from the conjunctiva, but this is rare. The intact, healthy conjunctiva is never infected by bacilli; there must always first be a loss of substance. In many cases, relatively, the conjunctival tuberculosis long remains the sole localization, and the early destruction of the neoplasm may lead to recovery. When an abrasion of the conjunctiva exists, it may become inoculated with bacilli from the lids, the nose, or the lungs, and an ulcer develops at the point of inoculation. The lesion usually begins in the tarsal conjunctiva of the upper lid, or in the retrotarsal fold. The lid is more or less swollen, and on eversion shows a punched-out ulcer with gray base, or a base covered with small, gray, miliary tubercles. These ulcers have ragged edges, and the bottom has a worm-eaten appearance and is covered by detritus. The small nodules may be in the edge of the ulcer instead of on the floor, and vary much in size. These ulcers sometimes bleed on handling. The pre-auricular gland is almost always involved, and sometimes the submaxillary also. The ulcers may be unilateral or bilateral, and may spread to the ocular conjunctiva and sclera, and thus serve as a focus for dissemination of a general infection, though absolute proof of this is still wanting. The eyelids are sometimes much swollen, but are soft to the touch, and the conjunctiva shows distinct folds around the ulcerated tuberculous mass. There is usually a slight purulent discharge in which the bacilli are sometimes found, but even in the tuberculous nodules they are often searched for in vain. According to the latest accounts about sixty cases have been reported, of which eight were published in 1900. All were between the ages of ten and thirty years, and there were more females than males affected. In a number of the cases the lesion was bilateral. It is exceptional to detect tubercle bacilli in microscopical sections of the ulcerated tissues (though they may be found in the scrapings from the floor of the ulcers), and well-defined giant cells are not always met with. The ulcers also vary clinically in appearance. Some of them are sharply cut, with irregular margins and yellow base, and surrounded by a zone of infiltration. Others present a more diffuse form, with small elevations of the mucous membrane which are frequently ulcerated. Whether the conjunctival disease be primary or secondary, it is quite conceivable that the tubercle bacillus may be conveyed into the nose from disintegrating pieces of conjunctiva, and cause infection of the mucous membrane of the nasal duct and nose. The neighboring lymph glands have not always been found swollen, though it is very possible that the swelling may have existed and been overlooked, and then have subsided as the local disease has receded.

The differential diagnosis is not always easy. Yellowish nodules sometimes develop in the vicinity, giving a granular appearance to the conjunctiva, resembling a case of trachoma. Tuberculosis of the conjunctiva must be differentiated from trachoma, epithelioma, and syphilitic ulceration. In trachoma the glands are not involved, and in acute cases the granulations will yield to treatment by caustics and astringents, while these are useless in tuberculosis. If we accept the dictum of Rhein that the follicles of trachoma and those of tubercle are analogous, the latter must then be differentiated by the presence of bacilli. Tubercle may be distinguished from epithelioma by the age of the patient. In true granuloma the granulation is a firm, reddish, vascular mass of uniform character, and the lymph glands are not involved. In brief, the character of the ulceration, the lardaceous aspect of the mucous membrane, the presence of peripheral tuberculous nodules, and the engorgement of the glands will usually suffice to differentiate the case; and if bacilli are found in the scrapings of the ulcer the diagnosis is confirmed.

Some very interesting experiments in inoculation were made by Langhans in 1873. He made sixteen inoculations of tubercle in the conjunctiva of the rabbit with varying results. Some were entirely negative. In others there appeared at the point of inoculation a translucent swelling formed of grayish-red nodules, ending in an ulcer with flat edges and pultaceous base. In a third series of cases, after a period of incubation ranging from twenty-one to thirty-four days, there appeared yellowish granulations which became red but did not ulcerate, and some of these animals became tuberculous.

Prognosis: If the case is one of primary infection and is seen early in its course the prognosis is fairly favorable, provided the local lesion can be thoroughly cauterized or excised. If the ulceration is secondary the prognosis is always unfavorable.

[1] Read before the New York State Medical Association, October 17, 1900.

Treatment: If the ulceration is single and removed from the lid margin, the whole ulcerated surface should be cauterized with the actual or galvano-cautery, and then the case carefully watched and the cauterization repeated if necessary. If the ulcer is close to the edge of the lid, the parts, including the entire thickness of the lid, should be thoroughly excised, and a plastic operation subsequently made to correct the resulting deformity.

Tuberculosis of the Eyelid appears in the form of lupus, usually along the ciliary margin of the lid, and soon involves the conjunctiva. The doctrine that lupus and tuberculosis are one and the same disease is now generally accepted, giant cells and bacilli being found in both. It may be primary or secondary. If primary it is due to direct infection from a foreign body or to operation. The disease is found mostly in children, but may occur at any age. On its first appearance it simulates an inflamed chalazion.

Prognosis: If the lesion is primary the prognosis is good. If secondary it is unfavorable.

Treatment: Thorough excision of the infected part is the only thing that promises any real cure.

Tuberculosis of the Sclera is occasionally met with in the form of nodules, coincident with nodules in the iris and ciliary body. As an independent lesion it is very rare, one case having been reported by Müller in 1890. The sclera may also become involved in the ulceration of tuberculous nodules of the ocular conjunctiva. The prognosis is unfavorable. The only treatment which would seem to promise a cure is enucleation of the eyeball. Instances of treatment by antitoxin have been too few, and the results not sufficiently favorable, to enable us to draw any satisfactory conclusion.

Tuberculosis of the Cornea.—The cornea is much less liable to tuberculous disease than any other tissue of the eye except the lens. Tuberculous nodules may develop primarily in the marginal zone of the cornea, and extend toward its centre. These small growths have been observed as the result of inoculation, and in the course of spontaneous tubercle of the iris. Panas has reported a single case occurring in a woman aged thirty years, of delicate health, with disease in the apices of both lungs. After sharp pain in the right eye, there appeared a diffuse interstitial opacity in the superior segment of the cornea, with episcleral injection. On the thirteenth day the disease had reached the centre of the cornea, and around the opacity were a series of yellowish nodules resembling miliary tubercles. These gradually coalesced, and in the fourth week the whole infiltration was ulcerated, with a yellow base and irregular edges. Each advance of the ulcer was preceded by new marginal tubercles. At the end it cicatrized densely opaque. Panas made some experiments in corneal inoculation in animals, and the course followed resembled very closely that noted in his patient. A tuberculous tendency may be suspected in cases of non-inflammatory abscess of the cornea, in scrofulous children, which shows no tendency to healing, even when there are no positive signs of tuberculosis present.

Tuberculosis of the Uveal Tract.—Tuberculous disease here may be either primary or secondary, the latter being much the more frequent of the two; and the patients are more usually found among those suffering from the chronic pulmonary, osseous, or cutaneous forms of the disease than among those affected with rapid general tuberculosis. In the uveal tract the nodules may be either miliary and disseminated, or in circumscribed small masses, or in solitary nodules. Small gray nodules appear and disappear, and either terminate in healing, or gradually extend to suppuration, perforation, and destruction of the eyeball.

Tuberculosis of the Iris and Ciliary Body.—Tuberculous disease of the iris occurs most frequently between the ages of five and twenty-five years. It may be either primary or secondary, the latter being the more frequent. Primary tuberculosis of the iris may be unilateral or bilateral. Haab recognizes two forms: one of rare occurrence and ending generally in a spontaneous cure; a second, much more common, ending in perforation and phthisis bulbi. The symptoms of either serous or plastic iritis are generally present. The diffuse form spreads rapidly, and generally invades the entire eye, and the cornea necroses and becomes perforated. This form usually occurs in patients predisposed by hereditary tendencies to the disease. The first or attenuated variety of the disease may recede and disappear without causing general infection. These cases of attenuated tuberculosis, in which the growths become absorbed and the eye partially regains its functions, are rare. The nodules are very small and scattered, are yellowish-gray in color, with a slight reddish tint due to the blood-vessels, and may involve the peripheral border or occupy the angle of the anterior chamber. Their course is very slow, with periods of amelioration and aggravation, and the case ends in a total disappearance of the nodules. Tuberculosis of the iris occurs usually in children as small grayish-red nodules at the ciliary margin of the iris, which look like miliary growths. The successive development of new nodules leads to plastic iritis and cyclitis, and then to a general shrinking.

The solitary tubercle of the iris, or so-called granuloma, begins as a small gray nodule, which slowly increases in size, fills the anterior chamber, perforates the cornea, and presents as a large granulation mass, and the eye is lost by general phthisis bulbi. The granulation mass always contains giant cells, and almost always bacilli. At first tubercles of the iris are composed of masses of small epithelioid cells, disposed concentrically round an obliterated vessel, and of a varying number of giant cells. After softening has begun, histology does not help much toward a diagnosis. If a case of tuberculosis of the iris is accompanied by blood in the anterior chamber, the disease has probably invaded the ciliary body, as hemorrhage from this quarter has been known to be the first symptom of tuberculous infection here.

Tuberculosis of the iris has been produced by inoculation of the anterior chamber in animals. Within three weeks of the inoculation the iris becomes inflamed, with the eruption of small grayish nodules which grow larger, coalesce, fill the anterior chamber, infiltrate the cornea, and cause perforation. The animals succumb later to a general tuberculosis. The intra-ocular tension is first increased, but later, as cyclitis develops, the tension falls below the normal standard.

Tuberculous growths in the iris may be confounded with gumma, sarcoma, and lepra. They may be distinguished from gummata by their color, their predilection for involving the inferior half of the iris, and by the presence of glandular enlargements and the usual signs of pulmonary tuberculosis. A tuberculous nodule may in its early stages be confounded with sarcoma, but the latter is almost certain to be solitary, is rarely accompanied by any iritis, seldom occurs before middle life, and is usually more vascular than a tuberculous nodule. In general, it may be stated that the lesion is probably tuberculous when the growths are multiple, non-vascular, and gray, and are accompanied by glandular enlargements. Iritis in a child is generally tuberculous and always serious.

The prognosis in cases of tuberculosis of the iris is always unfavorable, for none of the symptoms enable us to predicate the attenuated form of the disease.

Until we have had a larger experience, and have become more familiar with the nature and effects of tuberculin T.R. as an antitoxic agent, our only advice is to recommend enucleation. It is possible that iridectomy may be useful in the case of solitary tubercle before softening has begun, and will leave the patient with a varying amount of useful vision, but in all cases of multiple growths the eye should be removed.

Schieck has recently reported some interesting experiments with tuberculin.[1] He considers that tuberculin T.R. has shown much weaker symptoms of reaction than the first tuberculin, and thus the danger of general dissemination is lessened. Tuberculosis of the iris and cornea furnish the best conditions for the employment of the remedy, viz., local, unmixed forms of disease, and the absence of increased temperature. He reports five cases of his own so treated, varying in age from thirteen to twenty-eight years. All had the characteristic nodules at the periphery of the iris, and in three the lesion was bilateral. All were treated with tuberculin T.R., beginning with a dose of 0.002 mgm. and increasing each dose gradually from 0.002 to 0.5 mgm., and going as high in one case as 6 mgm. at a dose. In three of the cases the nodules rapidly disappeared, and all signs of inflammation subsided. In two cases all the symptoms of irritation were increased, while the nodules continued unchanged, but when the injections were discontinued they both healed promptly.

Schieck then gives the statistics of the results of treatment in 116 cases of tuberculosis of the iris. In the 13 cases treated by tuberculin injections all were improved and no eye was entirely lost. In the 103 cases which were not treated by tuberculin 39 were healed and 64 were lost. From this it would seem that the fear of the spread of the bacilli from a tuberculous nodule of the iris by the employment of Koch's tuberculin is not justified. It should be remembered that Koch's agent is not a bactericide, but merely supports the tissues and excites them to resistance in their conflict with the virus, while the bacilli are at the most but weakened. Hence the occurrence of a relapse should not be laid to the charge of the tuberculin. In nineteen reported cases in which an attempt was made to remove the local disease by iridectomy only eight were successful, four were total failures, and in the remaining seven cases the disease spread still more rapidly, due, doubtless, to fragments of tuberculous tissue left within the eye.

The second part of Schieck's work consisted in an endeavor to determine the effect of tuberculin T.R. upon cases of artificially produced tuberculosis of the iris and cornea, in order to see whether these disease processes induced in animals followed the same course as did the nodules in patients treated by tuberculin. The inoculation materials employed were fresh, pure cultures of human tuberculosis on glycerin-agar. He made a number of elaborate experiments on rabbits, divided into six different series. The results varied greatly in the different series, and even when apparently positive results were obtained, they were not entirely free from doubt. The most important fact established seemed to be the possibility of a spontaneous disappearance of tuberculous nodules of the iris in rabbits, a fact previously mentioned by Sattler.

Schieck formulates the results of his experiments as follows: (1) An immunizing effect of tuberculin T.R. does not exist. (2) Tuberculin T.R. cannot cure every case of experimental tuberculosis of the cornea or iris in the rabbit. (3) The cases treated by T.R. are no more malignant in their course than those in which T.R. is not used. (4) The study of the action of tuberculin in the rabbit cannot be an exact one, for undoubted cases of cure occur without the use of tuberculin.

If we compare our knowledge of the great value of tuberculin in cases of tuberculosis of the human iris with the very uncertain results of the experiments on animals, we find ourselves face to face with an inexplicable contradiction. Schiek endeavors to explain it as follows: In the disease process known as tuberculosis of the iris in man we have to deal with an insidious inflammation of endogenous origin, with the formation of nodules within the iris tissue itself, with few bacilli. On the other hand, the experimental tuberculosis of the iris starts from masses of bacilli which lie either free on the surface of the iris or in artificial wounds in the iris. The action of the tuberculin does not consist in killing the bacilli, but in exciting the surrounding tissue to resist the tuberculous masses and the formation of scar tissue. In the experimentally produced tuberculosis the bacilli are numerous and in the beginning lie outside the tissue, surrounded by a structure rich in cells but poor in connective tissue, and here the tuberculin has but slight effect. In tuberculosis of the human iris, however, the bacilli are few in number and the iris is abundantly rich in connective tissue, and here the tuberculin finds the most favorable conditions for its curative action.

Tuberculosis of the Chorioid.—Tubercles in the chorioid were first recognized by von Jaeger in 1855, shortly after the invention of the ophthalmoscope. They were supposed to be always secondary growths till 1873. They are met with under two forms: the miliary or disseminate tubercle, and the solitary or circumscribed. The former are usually found in the posterior part of the fundus, and the latter in the anterior part. They are most frequent before the age of twenty, and much more common in children than in young adults. The miliary form is met with in general acute tuberculosis and in tuberculous meningitis, while the circumscribed large masses of infiltration occur in chronic tuberculosis.

Miliary tubercles nearly always occur in both eyes. They vary in size from 0.5 mm. to 2.5 mm. in diameter, and are usually found in the vicinity of the optic nerve and macula lutea. They appear as round spots, pale yellow in color, with a pinkish zone shading gradually at the margin, and later become gray in color and somewhat prominent. They resemble recent patches of chorioiditis disseminata. They start in the deep layers of the chorioid, growing from the adventitia of the larger vessels, and, as a rule, cause no defect of vision. The older, large tubercles show under the microscope giant cells surrounded by a circle of nuclei, and these in turn are surrounded by a reticulum of fibres with small-cell infiltration, caseation, and extravasation of blood. The newer and small tubercles appear to be collections of lymphoid cells between the vessels. Bacilli are by no means always found. Their presence in the chorioid has no connection with the presence of tuberculous meningitis. They are said to be common occurrences in miliary tuberculosis, but the writer believes this to be an exaggeration. It is probable that tubercles of the chorioid which are visible with the ophthalmoscope belong to the terminal stage of general tuberculosis, as they often develop shortly before death. Owing to the small size of miliary tubercles, their tendency to develop in young children, and the consequent difficulty of examination, they are much oftener found after death than before it. Those which are readily visible with the ophthalmoscope are usually from six to ten in number, though they may reach as high as thirty or forty.

When the tuberculous deposit is in the anterior segment of the chorioid and takes on an acute process, it

[1] Archiv für Ophthalmologie, i., 2.

resembles an irido-cyclitis, and is accompanied by extensive destructive changes. It consists of a mass of tuberculous matter, which generally undergoes caseation, suppurates, and perforates the eyeball. The bacilli, when found, are relatively very few. Chronic tuberculous tumors of the brain are sometimes accompanied by tubercles of large size and slow growth in the chorioid, which gradually fill the eye and simulate malignant tumors. They tend to perforate the eyeball, usually anteriorly in the ciliary region, but sometimes extend backward along the sheath of the optic nerve. Extension downward along the same course from a tuberculous mass in the brain has been known to occur, but is not common. General tuberculous infection from these cases has been observed only when the eyeball has ruptured, and the orbital tissue has become infected. Hence the advisability of an early enucleation. The chronic miliary form progresses slowly and insidiously, the capillaries become obliterated, there is no pain, and very rarely any external evidence of disease, such as episcleral injection, is observed. It should not be forgotten that while miliary tubercles of the chorioid are sometimes found in connection with tuberculous meningitis, they are more frequently met with in general tuberculosis without meningitis. In any case they are comparatively rare, and while their absence is of no significance, their presence is valuable evidence of general tuberculosis. Owing to their rapid development, ophthalmoscopic examinations in suspected cases should be frequently and repeatedly made.

Tuberculosis of the Retina and Optic Nerve.—Tuberculous lesions in the retina and optic nerve are almost always associated with tuberculous meningitis, and in about fifteen per cent. of the cases of meningitis, miliary tubercles are found in the chorioid. When these are found in doubtful cases of meningitis, the differential diagnosis between typhoid fever and tuberculous meningitis may be considered as made. Moreover, myosis is frequently a symptom in the early stages of tuberculous meningitis, just as its opposite, mydriasis, is in the later stages, and a rapid oscillation between myosis and mydriasis is rather characteristic of the disease. In these cases there is a peculiar marbled reflection in the retina near the veins in conjunction with the tubercles in the chorioid, associated with œdema of the retina and optic nerve. There are also occasionally seen near the optic nerve some small white spots, the so-called retinal tubercles, but these are rare. Unequivocal tubercles in the retina are usually associated with tuberculous growths in all the structures of the eye.

The subjective symptoms in complications of the retina and optic nerve are periodical obscurations of vision and photopsia, and to these is sometimes added the objective symptom of papillitis. The optic nerve often remains normal throughout the entire course of the disease, but there are some changes in about half of the cases. The disc becomes red and the outline hazy, with more or less marked striation on the papilla and in the retina. It is more a neuritis than a papillitis, and hemorrhages are rare. There is a gauze-like opacity over the disc and retina, resembling that seen in syphilitic retinitis. The changes are always bilateral, and in most cases the patients soon die. In those who recover the intra-ocular signs are slight. The neuritis is a typical descending neuritis, the sheath of the nerve being not only distended but inflamed. In many cases the symptoms of meningitis are distinctly marked before the ocular changes occur. In some cases the cerebral symptoms are latent or doubtful, and here the ophthalmoscope affords assistance. A diminution in the severity of the cerebral symptoms may be accompanied by a diminution in the ocular changes. It should be remembered that optic neuritis is more commonly present in this form of meningitis than in any other, and, in consequence of its tendency to attack the base of the brain, paralyses of the ocular muscles are frequently met with.

Tuberculosis of the Orbit and Orbital Walls.—No case has ever been reported of primary tuberculosis starting in the orbital tissue. In the cases in which this tissue has been involved, the disease has started either in the iris or ciliary body, and the orbital tissue has become infected by perforation of the eyeball. As regards the bony walls of the orbit, the presence of periostitis or caries, when non-traumatic in origin, should excite suspicion of either syphilis or tuberculosis, especially in children.

THE TREATMENT OF TUMORS BY ELECTROLYSIS.

By WILLIAM B. NEFTEL, M.D.,
NEW YORK.

It may not be generally known that the real originator of the electrolytic and galvano-caustic methods of treatment was Gustav Crussel, a medical practitioner in St. Petersburg. He made his researches in the forties under the guidance of my celebrated teachers, the anatomist and surgeon Pirogoff and the physicist Lenz, but his admirable work passed unnoticed at the time. Ten years later Middeldorpf reintroduced the galvano-caustic method, which, with the improved apparatus and technique, was adopted by surgeons, while the electrolytic method of Crussel remained unknown, although he completely and with remarkable correctness laid down the rational indications for its employment. The interest of the profession was awakened only much later, when several physicians independently and almost simultaneously reintroduced the method in special morbid conditions.

I too must confess to an entire ignorance of Crussel's investigations during the first years of my experimental work, and shall always regret it; as a previous acquaintance with his writings would have spared me much time and troublesome experimenting. While recommending the historical study of electricity, I do not ascribe to it the same importance as to personal observation and experiment. My first electrolytic experiments on animal fluids and tissues gave me most valuable suggestions, which I was later able to verify during my long practice. The hardening, coagulating, shrinking effect of the anode offered itself at once for the treatment of aneurisms, varicose veins, cavernous tumors; while the softening, solvent action of the cathode seemed indicated in strictures and tumors.[1]

In this country, my lamented friends the late Drs. J. Marion Sims, A. Post, Nott, Mussey, also Dr. Bailey of Albany, Dr. Whitehead of Colorado, Drs. Jones and Graham of North Carolina, and others, sent me a number of interesting cases of tumor. I was thus enabled to study the electrolytic process from the clinical, biological, and physico-chemical standpoints, these latter in my private laboratory.

The first thing that surprised every surgeon who attended the electrolytic treatment was the slight general and local reaction following the operations. The patients, as a rule, continued their mode of living and their daily occupation. Even after severe electrolytic operations, as, for instance, the necrotic destruction of large malignant tumors in one sitting, by my method, under the influence of an anæsthetic, the general effect

[1] I made these observations while studying pathological histology in Virchow's Institute in the years 1860, 1861, and 1862, and examining the action of different electric currents on living unicellular organisms (amœbæ) and other protoplasmatic structures (leucocytes, sarcoma and cancer cells).

is comparatively insignificant—a very slight elevation of temperature, if any at all, one or two days in bed, moderate pain not requiring narcotics; sleep, appetite, and digestion remaining normal. After the removal of the necrosed tumor the wound rapidly healed by granulation, leaving a small, soft cicatrix.

The impression produced upon me by the electrolytic operations can be readily understood, considering the many years I spent in the clinics of Pirogoff and Langenbeck, in visiting the wards of celebrated English and French surgeons, and in performing surgical operations in the hospitals of St. Petersburg and during the Crimean war; all this before the antiseptic era of Lister. As no pyæmia, septicæmia, hospital gangrene, acute purulent œdema, etc., ever followed my electrolytic operations, I concluded that they are generally void of danger. I expected great results from the adoption of electrolysis in general surgery, but the brilliant results of the antiseptic method made such an innovation apparently unnecessary; I say apparently, because the electrolytic method not only remains applicable in many instances, but sometimes proves preferable to the usual surgical operations.

For convenience' sake I may here explain the immunity from complications which so often accompanied former surgical operations, although this should perhaps be said in connection with the physico-chemical phenomena of electrolysis.

I always ascribed an important rôle to the gases developed in electrolysis of living animal tissues. As long ago as 1840 Schoenbein discovered that a certain amount of the oxygen evolved at the anode passes in its active condition, which he called ozone, while a much larger amount of the oxygen combines with the hydrogen of the electrolyte and produces peroxide of hydrogen. Both the ozone and the hydrogen peroxide are easily recognizable by their reactions. The amount of these gases of course increases with the current intensity.

In order to examine the properties of the hydrogen developed at the cathode it is best to use a cathode of palladium, because, according to Graham, this metal absorbs a very large amount of hydrogen. The hydrogen thus obtained reduces in the dark the iron oxide salts and organic substances, and readily combines in the dark with chlorine and iodine; therefore, it is more active than the ordinary hydrogen gas. Such active hydrogen, according to Hoppe-Seyler, is able to cause strong oxidations by rendering active (ozonizing) the oxygen of the air and of the electrolyzed fluid. The effect of the active hydrogen evolved by electrolysis is thus more potent than that of the active oxygen (ozone), as the former calls forth oxidations as well as reductions. It is evident that the ozone, the active hydrogen, the peroxide of hydrogen, the chlorine, being powerful antiseptics and bactericides, render the electrolytic process a most efficient antiseptic. The accumulated acids also contribute their share to the antiseptic result.

The above facts explain the absence of septic phenomena, both local and general, after electrolytic operations.

I became acquainted with these properties of electrolysis very early in my practice, but only after many years of laboratory work I published them in detail in Virchow's *Archiv* in 1881.[1]

Not long ago my views were confirmed by the excellent researches conducted by Smirnow in the St. Petersburg institute of experimental pathology. He demonstrated, besides, that electrolysis is not only a bactericide, but destroys the toxins and transforms them into antitoxins.

[1] More recently Apostoli, with the aid of a bacteriologist, published as a new discovery the antiseptic and bactericidal action of the anode only.

The electrolytic process is the ideal antiseptic, since it can reach the most hidden places and cavities inaccessible to other antiseptics. The electric current being able to permeate the surrounding tissues, electrolysis is therefore especially indicated in the treatment of malignant tumors.

Owing to the work and discoveries of Arrhenius, Van t'Hoff, Ostwald, Raoult, and others, a new scientific branch—physical chemistry—has been developed within these twenty years, especially in the last decade, on the border lines of chemistry, physics, and physiology. This new science, of great theoretical interest, offers an inexhaustible source for new researches and discoveries, and is intimately connected with physiology and medicine (the modern theories of solutions, osmosis, cryoscopy, tonometry, the theory of ions, etc.).

The limits of this article permit me to give but a few elementary facts indispensable for the rational employment of electrolysis in medicine and surgery. Electrolysis, far more than the electrical phenomena in metallic conductors, affords an insight into the nature of electricity in general, and reveals the physico-chemical changes which take place in the living body under the influence of electric currents.

Substances which conduct the current are divided, as is generally known, into conductors of the first and second class. The conductors of the first class form a well-defined group characterized by the following properties: They are the only chemically simple bodies which in the solid state conduct the current. They conduct it with an incomparably greater velocity than do the conductors of the second class, and they conduct better at a lower than at a higher temperature, and without undergoing any change in their substance, except the elevation of temperature. To this group belong the metals and their alloys and amalgams, hence the name metallic conductors. All other chemically simple bodies in a solid state do not conduct the current, and are designated as non-conductors of electricity—insulators. The conductors of the second class, or moist conductors, are always compound chemical substances. They conduct the current only in a dissolved or fused condition, invariably under decomposition of their constituent parts (electrolysis), and are therefore called electrolytes. They conduct the current better at a higher than at a lower temperature. The conductors of the second class, moist conductors, electrolytes, carry the electric current because of their chemical decomposition. Substances which do not undergo electrolytic decomposition, like absolute alcohol, chemically pure water, etc., do not conduct the current. If these substances be connected with the poles of a battery of any strength no electrolytic decomposition will take place, nor will the needle of the intercalated galvanometer be deflected. On the other hand, even electrolytes will not be decomposed by the current as long as their molecules remain immovable, solid substances; but as soon as they are dissolved they immediately undergo electrolytic decomposition. Thus acidulated or saline water conducts the current and is decomposed by it so long as the water retains its liquid condition, but when in the state of ice it can neither conduct the current nor be decomposed by it. Hence it follows that both the animal fluids, which are saline aqueous solutions, and the animal tissues impregnated by them, are electrolytes and readily undergo the electrolytic action of the current. Even the compact bones and cartilages yield to it; for, besides medullary tissue and soft cellular elements, the living bones contain blood-vessels and canals filled with electrolyzable saline solutions. This is especially the case with the proliferating tumors in softened bones and cartilages.

The decomposition of an electrolyte is not merely a

phenomenon accompanying the electric current, but is the essence of electric conduction; for electric conduction is inseparable from chemical decomposition, and, according to Faraday's law, the amount of the decomposed electrolyte is directly proportional to the quantity of electricity which traversed it.

The fundamental condition of all electrical phenomena in moist conductors is the presence of free ions. The ions are specific atoms and molecules temporarily charged with electric energy. But as energy is constantly undergoing transformation (the transformations of energy really constituting all the phenomena in nature) the ions may lose their specific properties and again become ordinary atoms and molecules. The electrolytic decomposition is of a peculiar nature and differs from other decompositions by producing special electrical elements, ions entirely unlike, for the time being, any ordinary chemical bodies. A large category of substances cannot undergo electrolytic decomposition and are impassable for the electric current; as, for instance, alcohol, ether, petroleum, glycerin, oils, and other organic fluids, etc. It is therefore evident that not every material atom and molecule can become an electric element, an ion. However restricted, the class of electrolytes is still very numerous, as it comprises the solutions of salts, acids, and bases. The ions are the only carriers of electricity in its passage through solutions. When a solution contains no ions the electric current cannot pass it. If the solvent fluid is an insulator the electric charge of the ions is retained by them and cannot leave them so long as they are surrounded by the insulating solvent. The chemical constitution of the ions, after they have lost their electric charge and have become ordinary chemical bodies, is that of salts in the modern sense of the term. The ions developed by electrolysis and temporarily charged with electricity have for material basis on one side a metal or hydrogen, on the other a simple radical or a radical group or hydroxyl. For instance, in subjecting to electrolysis solutions of salts, acids, or bases, the metals Cu, K, Na, etc., or H are cathions and are attracted by the negative electrode, the radicals SO_4, OH, Cl, etc., are anions and are attracted by the positive electrode. At the respective electrodes the ions discharge their electricity and become again free, electrically neutral, chemical bodies, with their former properties and affinities, and immediately undergo secondary chemical combinations with the surrounding media, which they were incapable of while charged with electricity as ions. Thus, for instance, a sodium ion does not decompose water as does the sodium metal, a chlorine ion has neither the odor, nor the color, nor the affinity of chlorine gas.

Until recently a prominent feature of the electrolytic process was inexplicable, namely, the presence of products of electrolytic decomposition only at the electrodes, while the intermediate part of the electrolyte remained unaltered. Many theories were offered in its explanation, but it was left to Arrhenius to elucidate the facts fully and explain this and other phenomena in electro-chemistry.

His theory presupposes the existence of dissociated molecules in every solution of a chemical compound, even before it is traversed by a current, the dissociation being produced by the heat absorbed during the process of solution. Thus, when salts, acids, or bases are dissolved, they will not be present any more in the solution as compound chemical bodies, but their constituent atoms alone will be found in the solution. For instance, if we dissolve hydrochloric acid or sodium iodide, etc., the solution, if sufficiently diluted, will not contain these substances in their compound state, but their dissociated atoms of hydrogen or sodium, of chlorine or iodine, etc., in the form of free ions, the first charged with positive, the latter with negative electricity. If such solutions be subjected to the action of a constant current the cathions will be immediately attracted to the cathode, the anions to the anode, and both will discharge their electricity at their respective electrodes; after which they return to the state of ordinary bodies with all their natural chemical properties and affinities, as hydrogen, chlorine, sodium, etc., in statu nascendi, and enter into secondary chemical combinations.

The theory of ions, advanced by Arrhenius in 1887, generalizes the laws of osmosis discovered by Dutrochet, Pfeffer, and De Vries for substances which are not electrolytes, and makes them applicable to all other bodies. In like manner, it generalizes the laws concerning the freezing-point of solutions and the tension of their vapors, and explains a great many phenomena of paramount importance to physics, physiology, and medicine, which until then remained obscure and without connection.

The human body, taken as a whole, is a moist conductor, an electrolyte, consisting of about seventy per cent. of water which constitutes the general solvent fluid of the substances circulating in the system, viz., the inorganic salts—sodium chloride, potassium chloride, phosphates, sulphates, and carbonates of sodium, potassium, calcium, and magnesium, with salts of iron. There are, besides a fraction of sugar in the blood, the products of the albuminous tissue change—urea, uric acid, creatin, etc. The albuminous substances occupy a distinct place on account of their extremely complex chemical composition, the great number of atoms contained in their molecules, and their physical peculiarity as regards solubility. They belong to the so-called colloid substances and do not, like the salts, form a genuine aqueous solution, but gradually absorb water until they form a fluid from which they cannot be obtained either by crystallization or diffusion.

Of special importance in electrolysis of animal tissues is water, the combination of hydrogen (H) with hydroxyl (OH), which is not only the general solvent but is itself an electrolyzable fluid. The tendency to dissociation, and hence the conductibility, varies in different electrolytes. While hydrogen and hydroxyl possess but a slight tendency to dissociate into free ions, sodium chloride and potassium chloride dissociate quite readily. Thus the salts contained in the tissues undergo electrolytic decomposition while their solvent vehicle still remains intact.

The velocity of the current increases with the electromotor force and diminishes with the increasing resistance. The greater the mobility of the solution the less the resistance. This is why moist conductors, contrary to metals, conduct better at a higher temperature. The resistance depends also on the nature of the ions; the larger they are the greater will be the resistance. The size of the ions depends on their chemical composition and the number of their atoms. With the increase of the number of atoms the surface of the ions grows and presents a greater resistance to friction.

Since the molecules of albuminous substances contain hundreds of atoms and thus hardly conduct the current, it is evident that, contrary to the prevailing fallacy, they can play no part in the electrolytic decomposition of animal tissues.

The constituent parts of animal tissues in regard to electrolysis may be divided into two groups: the electrically inactive, to which belong the colloid substances and the non-dissociated ions offering only resistance to the current, and the electrically active, the dissociated ions which alone conduct the current. Among these chlorine and sodium are prominent for their tendency to dissociate, and, assisted by the water of the tissues, they principally accomplish the electrolytic decomposition in living tissues. The sodium

metal at the cathode, unlike the sodium ion, abstracts hydroxyl from the water of the solution and forms caustic soda, setting free the hydrogen; at the anode the chlorine gas, unlike the chlorine ion, takes the hydrogen from the water, forms hydrochloric acid, and lets the oxygen escape. Twice as much hydrogen is liberated at the cathode, as oxygen at the anode. The products of electrolytic decomposition of all the other salts, acids, bases, and water of the tissues react in an analogous manner. It is obvious that the accumulated alkalies at the cathode and the acids at the anode must produce a powerful destructive chemical effect, especially on the albuminous substances, where it manifests itself by discoloration, coagulation, disintegration, and necrosis. But these phenomena at the electrodes are the secondary effects called forth by the chemical products of electrolytic decomposition of the living tissues. The same process takes place everywhere between the electrodes, although invisibly in a molecular form. For it must be borne in mind that the living body which the electrolyzing current has to pass is not a homogeneous moist conductor, but consists of a great variety of organs, membranes, even single cells, and different concentrations of the aqueous solutions, all of which act as so many entrances and exits for the current—as anodes and cathodes. At each of these innumerable electrodes the water, the hyaloid salts, etc., undergo the same chemical decomposition as at the principal electrodes, the secondary chemical combinations excepted. This can be illustrated by a simple experiment. If a constant current is sent through a series of different solutions, decomposition takes place in the solutions, not only at the entrance and exit of the electrodes, but in each of the intermediate solutions as well.

The secondary chemical effects of electrolysis, which manifest themselves at the electrodes, are accountable for the local effects in the treatment of tumors; but equally important are the general molecular constitutional effects of electrolysis which take place between the electrodes in the whole body, in proportion to the density of the current. The local caustic effects at the electrodes can be intentionally eliminated by intercalating another moist conductor between the body and the electrodes, thus making available only the general constitutional effect.

The electric current in passing through living tissues is not entirely expended in the dissociation and transmission of the ions, but a portion of the current is transformed into other energies; an insignificant part into heat, owing to the small intensities employed, and a much greater part for the transformation of the electrical into mechanical energy—cataphoresis. This consists in an uninterrupted flow in the direction of the positive current of the whole mass of the electrolyte, including the electrically inactive molecules. Cataphoric action has quite a different character from the motion of the ions, it is not accompanied by decomposition, and it increases with the resistance. It has, however, one point in common with the electrolytic action—it is directly proportional to the intensity of the current. If a fluid through which a constant current passes be intercepted at some place by a porous diaphragm or a membrane, the fluid will flow through in the direction of the positive current and carry with it any particles that may be suspended, as if the diaphragm did not exist. The fluid sinks at the anode and rises at the cathode. Such a diaphragm offers a new resistance to the passing of the electric current, and therefore increases the cataphoric action. In the living body, where the current has to encounter innumerable membranes (diaphragms), the conditions are very favorable for cataphoresis. I often avail myself of the cataphoric action of the current, for instance, in the treatment of chronic swellings, especially of lymphatic glands. I apply to the swollen part percutaneously a small anode, and at a certain distance a large cathode, and allow the current to flow uninterruptedly for several minutes, and occasionally move slowly the cathode from one place to another. After each application the swelling diminishes at the anode, and the accumulated fluid with the suspended particles, carried by the cataphoric action of the current to the cathode, gradually disappears by diffusion and absorption. In my first attempts to treat malignant tumors more than thirty years ago, I tried to enhance the electrolytic action by introducing cataphorically into the substance of the tumor metallic salts (of zinc), but soon found it useless, the electrolytic action alone being entirely sufficient when properly employed. Whenever electrolysis is unable to cure the tumor owing to the generalization of the disease, cataphoresis of metallic salts is powerless to improve the result.

It may be proper to say here a few words regarding the relation of induction currents to electrolysis, or better, give the following simple experiment: If induction currents (currents in opposite directions in rapid succession) are made to pass through a voltameter the developed gases at the electrodes—oxygen, hydrogen, etc., constantly reunite and make the final electrolytic result very insignificant.

In the faradic current the opening currents prevail, and there is always a small excess of ions in this direction. Moreover, it displays the phenomena of cataphoresis, and in living tissues stimulates the nerves, produces muscular contractions, enhances the circulation and the absorption, and may thus contribute to the reduction of non-malignant tumors. On the whole, however, the electrolytic action of induction currents is insignificant and unfit for the reduction of large tumors, or for the destruction of malignant growths. The electrolytic action of the sinusoidal current and of static electricity is still less than that of the faradic current. For electrolysis of tumors, therefore, the constant current alone ought to be employed.

In living animal tissues (tumors) subjected to electrolysis by means of inserted needle electrodes the escape of fine, frothy gas (hydrogen) is observed at the cathode needle, the tissue immediately surrounding it becoming discolored, yellowish-gray, soft, and necrosed. The necrosed tissue is gradually dissolved in the accumulated free alkalies around the needle and forms a pale yellowish, odorless fluid of an alkaline reaction. Finally, the fluid is absorbed, and thus directly contributes toward the diminution of the tumor. By a considerable increase of the intensity and duration of the current a small, thin eschar is formed which dries and comes off. Within the sphere of the cathode the tumor at first becomes swollen, crepitating, and fluctuating, owing partly to the accumulation of gas and partly in consequence of the cataphoresis, but this swelling soon entirely disappears by absorption. Even very resistant tissues, in which the needle can be introduced only with considerable difficulty, become quite soft under the influence of the cathode after the current has flowed for a while, and allow the needle to penetrate easily in every direction. Therefore, the extraordinary hardness of a tumor does not contraindicate electrolysis.

Around the anode needle a dark, almost black, dry layer is formed, and consists of hard coagulated, shrivelled, mortified, or mummified tissue. This necrosed tissue likewise disappears gradually by molecular disintegration, by a kind of necrobiosis. But when the intensity of the current is great and its duration prolonged, a portion of the tumor surrounding the anode, or the entire tumor, may undergo necrotic destruction. Later on appears a slight inflammatory demarcation line, and after the necrotic mass has become detached

the defect rapidly fills up with healthy granulations and closes with a small, soft cicatrix.

As the action of the two electrodes is so widely different, it is imperative to warn against their indiscriminate use. Many times have I introduced the cathode needle into the substance of a myomatous uterus, the parenchyma of the spleen, the liver (ecchinococcus), the articular cavities, and for several seconds or even minutes kept increasing the current to a considerable extent, and without any unpleasant consequences. But quite different would be the result of a prolonged insertion of an anode needle; the necrosed mass would be eliminated in toto, which is not without danger. The anode needle of a strong current may remain inserted for a considerable time in such cases only when it is intended to effect a necrotic destruction en masse in connection with the surface of the body. When the anode needle is inserted for the purpose of coagulating the blood in aneurisms or varicose veins, it must not remain too long in the same place; or several branched anode needles may be used, which must be insulated at the contact with the tissues.

In electrolysis of tumors the contents of the blood- and lymph-vessels, being better conducting fluids, are especially affected by the current; the necrosis of the nutritive vessels greatly contributes to the regressive metamorphosis of the electrolyzed tumor.

For practical purposes tumors can be classified into malignant and non-malignant. The non-malignant tumors originate locally, and are caused by a local traumatic, mechanical, or chemical irritation. This calls forth hyperæmia and hyperplastic development of the irritated normal tissues. Such tumors produce per se no constitutional disturbance, but may become injurious only by their excessive growth interfering with the functions of the affected or the neighboring organs and with the circulation; but they do not invade the other organs and have no tendency to become generalized. Moreover, after complete extirpation they are not followed by relapses.

The origin of malignant tumors is due likewise to some local irritation, to which, however, is added the action of some parasitic micro-organism (protozoa, amœbæ, coccidia, etc.). Although the parasitic origin of malignant tumors is not yet generally accepted, the infectious nature of the disease points to this theory. Malignant tumors always invade the neighboring and distant tissues and organs; they become generalized, produce poisoning of the whole system (cachexia), and terminate fatally. Even the extirpation in the fully developed disease is of no avail, as it is followed by a relapse and generalization. This corroborates the theory of the parasitic origin of malignant tumors; for, however thorough the operation, the knife, caustics, or galvano-cautery cannot completely remove the infectious germs which remain infiltrated in the surrounding tissues and continue their work of destruction. Not so with benign tumors; for instance, a large fibromyoma of the uterus may remain during life without affecting the general health, but a small cancer of the cervix, or a little scirrhus nodule in the breast, in no way even interfering with the functions of the organ, are nevertheless disastrous to the general nutrition, produce cachexia, and invariably lead to death. With our present knowledge of the etiology of infectious diseases it seems plausible to attribute the essence of malignant tumors, their spreading, the general poisoning of the system, and other symptoms, to the vital activity of pathogenic micro-organisms. Moreover, the parasitismus of malignant tumors has been demonstrated by Jurgens, Sawchenko, Roncali. Doria found amœbæ in endometritis, which preceded the development of adenoma and carcinoma uteri, and quite recently Dr. Eisen, of San Francisco, demonstrated the constant presence of a certain amœba in epithelioma.

The electrolytic treatment of benign and malignant tumors, like their etiology, is based on radically different principles.

In treating malignant tumors by electrolysis my aim is to produce in one operation, by the action of the anode, the necrotic destruction of the tumor and of all the infectious germs of the surrounding tissues. This must be accomplished in the first stage of the disease, so long as the tumor is local, the lymphatic glands are not yet affected, and the distant organs are free from deposits. The effect of such an electrolytic operation is the disappearance of all morbid symptoms, and a complete recovery without relapses. A number of patients treated by me some twenty or more years ago are still in good health, although at the time the microscopical examination of the necrosed mass presented the characteristic structures of carcinoma. The operations were witnessed by physicians who kindly assisted me and observed the results.

I published the details of my method in Virchow's *Archiv*, vols. 57, 70, 86.

The treatment of benign tumors is based on a different principle. Here the indication is not to destroy the tumor by electrolysis, but to induce, by the action of the cathode, a regressive metamorphosis, molecular disintegration, absorption, and atrophy.

The following cases may serve as illustrations:

Mrs. C——, aged thirty-eight years, a childless widow of a good constitution but with an inherited tendency to obesity. Of late years she noticed a steady increase in the size of the abdomen and complained of dyspeptic symptoms, constipation, œdema of the lower extremities, and great discomfort in walking or driving. Both her father, a distinguished physician, and her brother-in-law, a well-known professor of surgery, diagnosed a very large fibroid tumor of the uterus, which filled the pelvic and a part of the abdominal cavities. They gave their opinion that an operation (extirpation of the uterus) was out of the question, as it would endanger life, and recommended rest and a careful mode of living as the best palliatives. I was consulted in 1878 in regard to electrolytic treatment, and made a favorable prognosis, based on experience with similar cases. I found the whole uterus, except the cervix, involved in the hyperplastic development, especially the posterior wall and fundus of the uterus; the posterior wall was quite hard and unyielding. At the first electrolytic operation, which I performed without an anæsthetic, a large flexible anode—a metallic plate well padded with compressed moss and flannel and soaked in warm water—was applied to the hypogastric region and a rather long and strong cathode needle of platinum introduced through the vagina. This needle was conveniently curved, and so insulated with soft-rubber tubing (not vulcanized) as to allow the metallic needle to penetrate at any desired depth into the substance of the tumor, or to be partially withdrawn and still remain insulated outside the uterus. I inserted the needle into the posterior wall of the tumor with considerable effort, because of the hardness of the fibromyoma at this place. The current was turned on with a minimum intensity, and was slowly and gradually increased by means of an excellent Hirschmann rheostat, when it was allowed to flow for about five minutes, then was gradually diminished and finally discontinued by the extraction of the needle at a very low current intensity. The whole current duration was about ten or twelve minutes, the operation was almost painless, and not a drop of blood was lost. The lady drove home from my office. She was advised to remain a few days in bed, without, however, changing her diet and without

any treatment, no fever or any other unpleasant symptoms having followed the operation.

Three electrolytic operations in all were performed at intervals of two or three weeks, with the only difference that the cathode needle was introduced at a different place each time with the highest current intensity of about one hundred and fifty milliamperes.

For after-treatment, I used galvanization of the splanchnic nerves—a method I described in Westphal's *Archiv* (vol. 10), and which influences favorably the circulation in the pelvic and abdominal organs, and is therefore employed by me in all chronic affections of the female pelvic organs. Besides I used faradization of the relaxed abdominal and perineal muscles, and of the ligaments of the uterus. The tumor soon began to diminish, digestion and other functions became normal. Œdema having entirely disappeared the patient regained her excellent health, which she continues to enjoy. I saw the patient occasionally during the next year after the operation and every time found a considerable reduction in the size of the uterus, until there remained only a circumscribed enlargement in the posterior wall of the uterus, which did not in the least trouble the patient. She has become again a good pedestrian, and passed through the change of life without any discomfort.

The method employed in the above case is generally adopted by me in the treatment of fibroid tumors of the uterus. My experiments taught me long ago that the tissue of myoma easily yields to electrolysis. I usually postpone each subsequent operation as long as the tumor continues to diminish, and until every trace of the inserted needle has disappeared. The intervals last from ten days to three weeks. The needles for electrolysis are always of platinum, which, besides being pliable, does not oxidize under ordinary circumstances, and, when used as an anode, they do not corrode or break and can be easily extracted.

My principal work in electrolysis, both experimental and practical, was published between 1868 and 1881, *i.e.*, before the introduction of the absolute galvanometer. I always worked, however, with the excellent apparatus of Krüger and Hirschmann, which contained a good current-selector, a commutator, rheotome, rheostat, Sieman's constant elements, and a good galvanoscope, indicating not only the presence and direction of the current but also its approximate intensity. In using this apparatus the number of resistances and the angle of deflection of the needle gave a tolerably accurate notion of the amount of the electric current.[1]

In this way Du Bois-Reymond, Pflüger, and others discovered the laws of electro-physiology; Brenner the normal and pathological reactions of the motor and auditory nerves; Erb the degeneration reaction; I described the galvanic reaction of the optic nerve, and the whole doctrine of electro-diagnostics was established before the introduction of the absolute galvanometer.

For scientific electro-therapeutics it is of the utmost importance to have an exact standard of measurement, although for daily practical purposes we may speak of weak, moderate, or strong currents, as we do of small, moderate, or large doses of a remedy; still more so in electro-therapeutics, since during a sitting we have constantly to change the intensity of the current. Besides in medical cases it is not so much the current intensity per se, as the insidious or abrupt way in which it is increased or diminished that is of consequence.

Generally speaking, I use from 20 to 200 milliamperes in treating benign tumors, and 30 to 1,000 milliamperes for malignant tumors, according to the nature and size of the tumor and the duration of the current.

As I purposely select illustrations from my old cases which have stood the test of time, I give the amount of electricity only approximately in milliamperes.

I discontinue the electrolytic operations when the tumor is still of considerable size, because the regressive metamorphosis, once fairly begun, as a rule progresses spontaneously, as in the following case:

In 1869 I was consulted by a married childless lady, about forty years old, who suffered from dysmenorrhœa ascribed to a retro-uterine fibroid tumor. I inserted into the tumor a cathode needle of a moderate current, and repeated the operation three times in two months. The dysmenorrhœa and all other morbid symptoms disappeared, and her general health improved. She had to go home (Chicago), expecting soon to return and resume the treatment, but had to stay away for more than a year, still feeling well. When she returned to New York I found only a small residuum of the tumor, and therefore informed her that all further treatment was unnecessary.

Since this experience I leave the further reduction of a tumor to nature and to the spontaneous regressive metamorphosis which has been induced by the electrolytic operations. The electrolytic effect is generally better when the operation is performed before the menstrual period.

When I first began to treat fibromyomata accompanied by profuse menstruation, I introduced on several occasions into the cervix a sound-like anode of a rather weak current; but the effect was more irritating locally and constitutionally than with my ordinary method; and as soon as I found that the insertion of the cathode needle, as practised by me, removed the hemorrhages together with all the morbid symptoms, I never afterward treated fibroid tumors through the canal of the cervix.

As mentioned above, my researches, conducted during many years, were published in Virchow's *Archiv*, the last exhaustive article appearing in 1881. They were all extensively quoted in the leading German, English, and French periodicals. In 1882, a year after the last publication of my work, Apostoli published his first article on the electrolytic treatment of fibroids of the uterus, followed by numerous articles on the subject in the principal cities of Europe and America.

His method of introducing a sound electrode into the cervix requires more frequent operations with strong currents, and is in so far injurious as it more or less destroys the mucous membrane, together with the glandular structures of the cervix, with all the harmful consequences, especially in case of a subsequent pregnancy. Still more serious is the insertion of the anode into the substance of the intramural fibroids, which may cause sloughing and even a fatal result. These disadvantages are absent in my method. The insertion of the cathode needle into the tumor is preferable to the introduction of the anode sound into the cervix; it is far more efficient and harmless; it is simple, more convenient, less painful, and free from injurious or dangerous effects.

I said previously that the electrolytic treatment is indicated not only in malignant neoplasms but in such cases in which the usual surgical operations are employed under great disadvantages; for instance, as in the following case:

Mrs. D——, of Boston, aged thirty-three years, an emaciated, cachectic-looking lady, consulted me in the spring of 1873 about an extremely painful affection of the left thumb, of fifteen years' standing. The intensest pain was concentrated at the base of the nail

[1] The great resistance of the epidermis need not be considered when needle electrodes are used. In percutaneous applications of the current the resistance of the epidermis is reduced to a minimum by saturating it with a tepid saline solution.

on the ulnar side. The patient compared the pain to toothache, but a great deal worse; she said it was as when the exposed nerve of a tooth came in contact with a metallic instrument. The pain was continuous, and increased at the slightest touch, so that she kept the thumb protected by the fingers even in sleep. The objective examination was possible only in deep narcosis, but nothing abnormal could be detected. The patient consulted the most distinguished neurologists and surgeons, and used all sorts of narcotics and constitutional treatments, without relief. She tried three different kinds of electrical treatment, and the galvano-cautery under an anæsthetic, and maintained that electricity aggravated her suffering every time. Finally, at the advice of eminent surgeons, among whom was Dr. Mussey, of Cincinnati, she decided to have the thumb amputated. Brown-Séquard objected on the ground that the pain might be of a central origin, and the amputation would not abolish the pain. Dr. Mussey then advised the patient to consult me before submitting to the operation.

With the assistance of Dr. Rogers, I made a thorough examination of the patient on May 15, 1873. The excruciating pain was concentrated at the base of the nail, and the spot could not be touched even under a superficial narcosis. There was no atrophy or other trophic symptom, no pain along any nerve either spontaneously or under pressure. The most careful examination under a complete anæsthesia gave the same result; nothing abnormal could be detected, no nodule or intumescence of any kind. It was obvious that the painful affection was not an ordinary neuralgia; again, it could not be a neuritis on account of the absence of any trophic or other neuritic symptoms; neither could it depend on a central cause, all central symptoms being absent. I thus came to the conclusion that there must be some miliary neuroma inaccessible to palpation owing to its small size, but which acted as an irritant on some sensitive nerve-filament, and I decided to use electrolysis, from which I had had excellent results in several cases of neuroma and tuberculum dolorosum.

Accordingly on June 4, 1873, after the patient had marked the painful spot with silver nitrate, I resorted to the electrolytic operation under profound anæsthesia. A flexible anode was placed around the forearm, and the cathode needle inserted into the painful spot as far as the bone; the current was rapidly increased to about two hundred milliamperes, and after about half a minute or so gradually decreased to zero and the needle extracted. No blood escaped, only a small grayish discoloration appeared around the needle. On awakening, the patient was delighted to find no pain even under pressure, felt very well and slept comfortably all night, enjoying the complete disappearance of suffering. The scab on coming off left no mark. The pain that had lasted day and night for more than fifteen years never returned (since 1873—now, 1900) after the apparently insignificant electrolytic operation of less than two minutes' duration. The patient belongs to an old Boston family, her case was known at the time to the profession of that city, and Dr. Mussey wrote me that he had been so impressed by the unexpected result that he concluded to try himself an electrolytic operation. He sent me the cast of a woman's wrist affected by cancer involving the bones, which he cured by electrolysis, after the general opinion of surgeons was to amputate the forearm.

I would add that neuromatous affections of this kind are of more frequent occurrence than is generally accepted. The "points douloureux" of Valleix, which are considered pathognomonic for genuine neuralgias, are, in some cases at least, not only a symptom, but the real cause of the neuralgia. I came to this conclusion from the favorable result of electrolysis in several obstinate neuralgias which had resisted previous treatments.

In the treatment of benign tumors of considerable size I often use the following method: After local anæsthesia I introduce the cathode needle into the tumor and apply a large anode at some distance from it, when the current is increased very slowly to a moderate intensity and after a few minutes gradually reduced to the minimum and the needle extracted. This procedure is repeated as often as advisable, with some modifications. No local anæsthesia is required after the first operation, the needle being inserted into the same place, but each time in a different direction in the tumor. The current intensity may be somewhat increased or diminished. These operations are perfectly painless, and do not inconvenience patients in their daily occupations. The insertion of the needle leaves no mark on the skin, and the tumor gradually diminishes and disappears. After a certain number of such needle operations the current may be applied percutaneously by means of a small flat cathode over the place where the needle was inserted in the previous operations. The current in its greatest intensity is thus conducted into the substance of the tumor along the lines made by the former insertions of the needle. In this painless manner I treated many benign tumors, including goitres, naso-pharyngeal and other tumors.

Mrs. B——, forty-five years old, and mother of five healthy children, was referred to me by Dr. Dunham, March 5, 1873. Both her parents died early (at thirty-three and forty-six years respectively) of pulmonary tuberculosis. The patient was formerly healthy, but had a goitre, the origin of which could be traced back to her early youth. It gradually increased until it attained considerable dimensions, and while it formerly had no unpleasant features, during the last few years morbid symptoms manifested themselves with increasing severity within the spheres of respiration and circulation. The struma occupied the anterior surface of the neck, especially the right side, the middle portion filled the jugulum sterni and, bulging out in an oval prominence, extended downward into the mediastinum. Its lower end could not be ascertained. The right sterno-mastoid muscle was pushed outward, and strong pulsations of the right carotid could be felt behind it. The right cervical veins were much dilated, the deeper cervical glands enlarged and indurated. Phenomena of paralysis of the right cervical sympathetic were very marked; the right eye, sunken, appeared smaller than the left, its pupil was contracted to the size of a pin's head (myosis), and ptosis of the right lid was present, the vision remaining normal. The patient complained of difficult breathing, especially when going upstairs or lying on the left side, and of pains in the left shoulder and arm. The area of cardiac dulness was enlarged, but there was no valvular affection. Evidently it was a case of mediastinal struma, and the paralytic phenomena of the right cervical sympathetic were caused by the pressure of the indurated glands. The patient was treated both here and in Europe with various remedies, the tumor being considered inoperable as it was impossible to remove its mediastinal portion.

In her case I resorted to the above-described method, and on April 16, 1873, after local anæsthesia, a cathode needle was introduced through the central portion of the struma—the part extending into the mediastinum—the flat anode applied at a distance, the current gradually increased to about fifty milliamperes and then diminished in a like manner, and the needle extracted. The operation was painless and lasted but ten minutes. It was repeated once or twice a week without anæsthetics, the needle being inserted into the same place, but each time in a different direction. On discontinuing the needle operations she was treated

percutaneously with a small cathode plate over the place of the needle insertion, and the anode as before. The treatment was discontinued after the struma was considerably reduced and the subjective symptoms had disappeared. Ten years later I had the opportunity to examine the patient, and found the same satisfactory conditions.

Miss B——, eighteen years old, a well-developed, regularly menstruated young lady, with an unhealthy complexion and anæmic. Four years ago a slight swelling was noticed in the right parotid region, and grew to the size of a hen's egg, extending into the space between the maxilla and sterno-mastoid. Although the tumor caused no pain, its steady growth was a source of great anxiety to her parents. There was every indication for surgical interference, but all agreed that the extirpation of the tumor would be fraught with danger on account of its intimate connection with important nerves and blood-vessels.

The case was referred to me by Dr. Thompson, of Indianapolis, and on October 17, 1878, I began the electrolytic treatment. The tumor in the right parotid was of a rather hard consistence, somewhat movable, and covered with normal skin (lymphoma). Besides this large lymphoma, all the cervical lymphatic glands of the same side were swollen. After local anæsthesia the cathode needle was introduced into the centre of the tumor, the flat anode placed over the swollen cervical glands, and from a minimum intensity the current was gradually increased to about thirty milliamperes, and in a couple of minutes diminished again and the needle extracted. There was no loss of blood, and the operation was painless; the patient with her parents left my office for their daily drive and walk in the park. These operations, but without anæsthesia, were repeated several times, and the needle curved to enter a different direction through the same puncture each time. Later, a mild current was daily applied with a small cathode plate over the spot of the needle insertions, and the anode on the different swollen cervical glands. Whenever the regressive mêtamorphosis seemed to come to a standstill, the needle operations were immediately resumed. This treatment was continued until the tumor entirely disappeared. The young lady, who attended school in New York, continued her studies without interruption, and, when she left for home in June, 1879, she was in perfect health. A few years ago I had the opportunity of seeing her as a married woman and mother of healthy children, without any trace of the former tumor.

The object of this paper is to elucidate the principles on which the electrolytic method is based. The space being limited, I have to omit its different modifications in various forms of benign tumors, leaving the details to be acquired by practice. I omit, too, the histories of many cases in which the electrolytic treatment was a mild, harmless, seemingly trifling procedure, which did not even disturb the patients in their daily occupations, and in which ordinary surgical operations could have been applied with equal success, but would have been of a far more difficult, troublesome, and serious nature.

I cannot conclude without calling attention to a very distressing surgical affection—hypertrophy and tumors of the prostate—in which I found electrolysis of great benefit. Soon after the success of electrolysis in fibromyomata of the uterus it occurred to me to employ the same in prostatic affections, since the prostata, from an embryological and histological standpoint, is the homologue of the uterus; three-fourths of its substance being muscular and one-fourth glandular tissue. Moreover, my earliest experiments on living animal tissues taught me that the unstriped muscular tissue most readily undergoes electrolytic action; *a priori*, therefore, it was a rational indication to employ electrolysis in prostatic affections.

Mr. T——, a robust, healthy-looking gentleman, fifty years old, gave me the history of his case. When a young man, in a course of athletic games, he received an injury in the perinæum which laid him up for six weeks. There was a painful inflammatory swelling, with fever and difficult micturition. An eminent surgeon considered serious the injury to the prostate, and treated him with leeches, poultices, cathartics, and prolonged rest. The patient recovered under this rational treatment, but for a long time there remained considerable tenderness in the perinæum, with a feeling as of some swelling, and an occasional slight impediment in passing water. These symptoms gradually wore off; he married and had several healthy children. About ten years ago the old symptoms began occasionally to return, especially after physical over-exertion or any other excess; unpleasant sensation in the perinæum, slow and difficult micturition gradually increased and became permanent. He was treated for enlargement of the prostate here, and later in London and Scotland, and received temporary relief from the introduction of metallic sounds; but on the whole the morbid symptoms kept on the increase. When he consulted me, he complained of discomfort in the perinæum and bladder, which he could never entirely empty; the micturition was slow and painful, the urine was turbid and contained a great deal of mucus, pus-corpuscles, and epithelia of the bladder. The patient said his urine was clear before the treatment with sounds. He evidently had cystitis and chronic hypertrophy of the prostate. I advised tepid irrigations of the bladder with antiseptic solutions, which relieved the acute inflammatory symptoms, while the enlargement of the prostate remained the same. I then began the electrolytic treatment. After the evacuation of the bowels with a saline aperient and an enema, I inserted into the substance of the prostate through the rectum a carefully insulated cathode needle, allowing but a small part of it—the very end—to be active. The anode plate was applied to the hypogastrium, and a very weak constant current was gradually increased to about fifty milliamperes, then decreased to zero in a few minutes when the needle was extracted. This treatment was repeated in a fortnight; in the interval and afterward galvano-faradization was used. A specially prepared cathode electrode was introduced into the rectum so that only a part of its cylindrical surface came in contact with the rectal portions contiguous to the prostate. The anode plate was applied to the hypogastrium as before. By means of a Hirschmann apparatus both the constant and faradic currents were used simultaneously with the same electrodes, allowing the currents to be increased, decreased, or reversed. Under this treatment the patient rapidly improved, the prostatic enlargement gradually diminished, the cystitis and all morbid symptoms disappeared and have not returned.

I often employ galvano-faradization in affections of the nervous and muscular system for the purpose of stimulating them while the nerves are in a state of electrotonus. In many chronic affections it greatly stimulates the circulation, absorption, osmotic pressure—in fact, all the physico-chemical phenomena and physiological functions. When used after electrolytic needle operations, it enhances the electrolytic and cataphoric action of the current. In affections of the abdominal and pelvic organs, too, galvano-faradization of the splanchnic nerves, which control and regulate the circulation and nutrition of these organs, is exceedingly beneficial. Altogether, the physiological and therapeutic effects of galvano-faradization are most remarkable.

Mr. L——, sixty-five years old, consulted me in

March, 1896, for prostatic enlargement with chronic cystitis which for many years resisted local and general treatment. The patient was of a sallow complexion, anæmic, emaciated, worn out by sleepless nights, owing to the bladder trouble. The enlarged prostate was tumor-like and hard, the urine very turbid and formed a massive, thick muco-purulent and gelatinous deposit. Tepid antiseptic irrigations, continued for a fortnight, gave relief, and I could proceed to the first electrolytic operation, performed as in the preceding case and twice repeated. Later, the insulated rectal cathode was applied to the prostate and the large anode to the hypogastric region and, as in the above case, strong galvanic and faradic currents were used simultaneously with frequent reversions. This was repeated three times, twice and once a week, and afterward only occasionally. The subjective symptoms disappeared toward the end of two months. Water could be retained for hours, and the patient could sleep comfortably. The prostatic enlargement was considerably reduced and the general health much improved. As an after-treatment I employed as usual the galvano-faradization of the splanchnic nerves.

In recent, less advanced cases of prostatic enlargement, and in the absence of cystitis, I entirely dispense with the needle operations and irrigations of the bladder, and use instead the rectal electrode with the anode at the hypogastric and inguinal regions and combined constant and faradic currents, as described above, and subsequently galvano-faradization of the splanchnic nerves. In mild cases even the rectal electrode gives way to a properly shaped cathode applied to the perinæum and the anode to the lumbar, hypogastric, and inguinal regions with strong galvano-faradization, as in the following case:

Mr. C——, aged fifty-eight years, noticed in the last few years a peculiar change in the voiding of the bladder; the flow became very slow, prolonged, with interruptions and a feeling of discomfort. His physicians found a considerable hypertrophy of the prostate; the urine was very concentrated, of a dark color, of high specific gravity, containing a large amount of indican and urates. In November, 1897, I began the electrolytic treatment of the prostatic enlargement, with a cathode of convenient shape applied to the perinæum and a large anode to the lumbar, hypogastric, and inguinal regions, and used strong galvanic and surging faradic currents simultaneously with frequent alternations, as previously described, until the complete disappearance of all morbid symptoms, and followed this by galvano-faradization of the splanchnic nerves. The gentleman continues in excellent health.

During these many years I did not publish my observations of prostatic enlargements. The cases treated by me with electrolysis—seventeen in all—may be considered too few to establish the value of a therapeutic method, but I give some of them because I believe that even one positive result is worth more than hundreds of negative ones, especially in prostatic affections, in which the available palliative is only castration or Bottini's operation.

As everywhere in practical medicine, the electrolytic treatment has to be adapted to the exigencies of each special case, and the physician often has to deviate from a general rule. Thus, I laid down the general indications for the treatment of malignant and non-malignant tumors as follows: Malignant neoplasms ought to be entirely destroyed in one sitting by the action of the anode, whereas in the non-malignant tumors a regressive metamorphosis, a gradual reduction, and atrophy should be induced by the action of the cathode. But I had to modify this procedure in some cases, as in the following:

Mr. E——, over sixty years old, of a good constitution, consulted me in October, 1899, about a small nodule, the size of a pea, at the right angle of the mouth, at the junction of the skin and mucous membrane, from which filiform elongations could be felt in different directions. More than a year ago he noticed a scarcely perceptible induration, which gradually reached its present size, and, to prevent its further growth, his family physician advised the removal of the nodule by the knife, as all external treatment was of no avail. Bearing in mind that the location of the nodule is frequently the seat of an epithelioma and that under the former treatment it showed no tendency to resolution or absorption, I was inclined to consider it of a malignant nature, although the neighboring lymphatics were not yet involved, and there were no other symptoms of malignancy. I introduced the cathode needle of a very weak current into the centre of the nodule to its basis, the anode plate under the chin, gradually increased the current to thirty milliamperes, and in a few seconds diminished it and extracted the needle. But I immediately reinserted the needle into the same puncture, giving it a different direction—into one of the elongations—and in a little while extracted it again to reintroduce it several times, once into each of the elongations, but always through the same opening. From my office the patient went directly down-town to attend to his business, as usual, and came every morning during that week, and three times the next week, when I applied for a few minutes a small cathode plate of a weak current over the place where the needle was inserted, the anode as before. A small scab came off leaving no mark on the skin, and the induration which had been gradually decreasing disappeared entirely. The operation left not the slightest trace. The gentleman is in excellent health.

Mr. M——, sixty years old, of good constitution, had a molluscum fibrosum, the size of a small plum, over the right shoulder. During the last year it became more or less troublesome and irritating; it changed color and occasionally bled. I found it red, with partial, dark pigmentation; the excrescence was connected with the common integument by a thin but rather hard pedicle in which could be felt the pulsation of a blood-vessel. Such a fibroma molluscum may remain in *statu quo* for life, or may sometimes assume a malignant course, especially in the pigmented variety as in this case. I operated in November, 1899, with the two needles of a bifurcated cathode inserted at the base of the fibroma, and the anode needle into the thick, soft, and pendulous end of the molluscum. A weak current was turned on, gradually increased to one hundred milliamperes and continued until the whole mass became livid and black, when the current was brought back to zero and the needle extracted. No blood escaped, and the pulsation ceased. The whole fibroid eventually shrivelled and mummified, and finally came off without leaving a trace of its former existence, or even a mark on the skin.

Thus the first of these cases, probably of a malignant nature, was treated like a non-malignant tumor by gradual absorption induced by the cathode needle. On the other hand, the fibroma molluscum, generally a benign tumor, was here treated as malignant by necrotic destruction of the whole, induced by the action of the anode.

I made this modification in the above cases on account of the location occupied by the tumors, their size, and the mode and degree of their development.

Cholera in India.—Cholera has been so bad in the Rampore state, India, that the Nawab has just sacrificed one of his elephants in the hope that the offering will appease the goddess of the disease.

INFANT FEEDING.[1]

By LOUIS FISCHER, M.D.,

ATTENDING PHYSICIAN TO THE CHILDREN'S SERVICE OF THE GERMAN POLIKLINIK, ETC.

Hand Feeding or Bottle Feeding.—The most important point to be considered in the proper management of bottle feeding is to have pure cow's milk. Such milk can be secured only from a reliable dairy, in which we are positive that all modern sanitary laws are so applied that the hygienic condition of the cow's stable is perfect. The principle of sterilization should be applied to everything in the stable—to the cow, to the milker's hands, and to all utensils used in milking and transportation exactly as was outlined by Professor Baginsky in his paper on "Milk Supply," which I had the honor to read at the last meeting of the section on diseases of children at Atlantic City in June, 1900. The principle of asepsis, so important in surgery, and which is really nothing more than absolute cleanliness, should be rigidly enforced.

Imitate nature in feeding. Nature has ordained for woman to feed her infant with raw milk, for it must be admitted that the breast milk of a woman is raw; it is neither boiled, nor sterilized, nor pasteurized. Thus we should simply imitate nature in feeding the milk of the cow in the same manner as the infant at the breast receives it from its mother or wetnurse.

Objections to Raw-Milk Feeding.—There is a decided objection to raw-milk feeding owing to the contamination of milk with various pathogenic bacteria. Such risk, however, is reduced to a minimum when all the principles of modern hygienic measures are rigidly enforced. It is a well-known fact that the prolonged use of sterilized or boiled milk will produce scurvy, and when scurvy exists both sterilized and boiled milk must be discontinued to give place to fresh raw milk. Does it not seem more plausible in the face of such clinical experience to commence feeding at once with raw milk rather than risk the development of scurvy and be compelled to discontinue all other forms of feeding excepting raw foods? There is a certain deadness, or, to put it differently, absence of freshness in milk that is boiled or sterilized. It seems to be the lack of this same element of freshness which in the absence of fresh meat and green vegetables will produce scurvy in the adult. Speaking of the development of scurvy in children fed on sterilized or boiled milk Rundlett says that changes take place not in the albumen, fat, or sugar; but in the albuminate of iron, phosphorus, and possibly in the fluorin, vital changes take place. These albuminoids are certainly in milk, derived as it is from tissues that contain them and are present in a vitalized form as proteids.

On boiling the change that takes place is due simply to the coagulation of the globulin or proteid molecule, which splits away from the inorganic molecule, and thus renders it as to the iron and fluorin unabsorbable, and as to the phosphatic molecule unassimilable. This is the change that is so vital, and it is this only which takes place when milk is boiled. It is evident that children require phosphatic and ferric proteids in a living form, which are contained only in raw milk.

Cheadle says that phosphate of lime is necessary to every tissue. No cell growth can go on without earthy phosphates; even the lowest form of life, such as fungi and bacteria, cannot grow if deprived of them. These salts of lime and magnesia are especially called for in the development of the bony structures.

General Rules for Infant Feeding.—Each child is a law unto itself, and its individual wants must be studied. One child will gain in weight on the same mixture on which another will lose in weight, thus proving the difference in the assimilation of the same food in various infants. Having chosen a given food for one infant, we must note the following factors, to be satisfied that it is thriving: First, the infant must appear satisfied after taking its bottle; second, there should be no vomiting; third, there should be no colic; fourth, the bowels must move unaided at least once or twice in twenty-four hours, depending upon the age of the infant; the stool should be yellowish-white and of a medium soft consistency; fifth, the infant should sleep from four to eight hours at one time during the night; sixth, the weight must be taken regularly once a week, and if an infant thrives it should gain at least six to eight ounces every week; seventh, when a child's weight shows no increase the reason should be studied, and by all means the food changed, for the infant requires more substantial nourishment. The following table will give an approximate idea of the quantity of food suitable for the age of the infant:

Age.	Quantity.	Proportion.	Frequency of Feeding.
1-2 months	2 ounces.	½ milk, ½ water.	Feed every 2 hours.
2-4 "	3 "	⅔ " ⅓ "	" 2 "
4-6 "	4-6 "	¾ " ¼ "	" 3 "
6-8 "	6-8 "	¼ " no "	" 3 or 4 "

Laboratory Milk.—The sentiments expressed at the last meeting of the Academy by Professor Jacobi, regarding the use of modified laboratory milk, coincide with my views. My experience has been that children fed on laboratory milk have been backward in their development, after its use for a long time. When first used, children suffered with severe constipation. Later, a distinct atony of the stomach and intestines was seen; poor appetites, requiring nux vomica, were seen still later, accompanied by delayed dentition and rickets. Children using the milk always looked pale and anæmic; their flesh was flabby. Such cases were among the wealthy, in which the best possible hygienic conditions prevailed. I have never had an opportunity to study its effect on infants reared in tenement houses, with the poorest hygienic surroundings. The percentage method of feeding has always appeared plausible to me, but the theory cannot be put into practice. We know, as Jacobi so well says, that mother's milk changes at almost each nursing, and we know by chemical analysis that mother's milk is different in composition several times during the day. It will be necessary then, if we do intend to imitate nature, to change the formula of an infant several times a day.

It is a fact well known to chemists that once an emulsion of milk is broken up by centrifuging or other mechanical process, as in separating the top milk from the skim milk, we cannot have again as homogeneous an emulsion as prior to this breaking up; and, moreover, that we increase our trouble when we in addition seek to improve the quality of the milk by subjecting it to the process of sterilization.

Substitute for Milk in Diseases of Stomach and Intestines.—When milk disagrees and the infant's stomach will not tolerate it, and vomiting is provoked, or when gastro-intestinal trouble arises, then milk must be stopped. At such times I have seen good results in many children follow the use of almond milk. This is made by scalding or blanching the almonds, then beating them up, using an ounce of water for each ounce of blanched almonds, and rubbing up this mixture and then expressing it through cheesecloth. This should yield an ounce of almond milk for each ounce of almonds used. It is well known that quite a large quantity of vegetable proteids are contained therein, and it is therefore a nourishing substitute. This almond milk can be made at home,

[1] Read before the stated meeting of the Academy of Medicine, at its Symposium on Infant Feeding, October 18, 1900.

and is quite serviceable in the treatment of summer complaint.

Dextrinization of Foods, Chiefly the Cereals.—Dextrinization is successful in children having subnormal gastric digestion. It should be used during illness only, and it is not advisable to feed healthy children with dextrinized foods. Nature supplies its own dextrinizing agents, which must be used or the glands secreting them will become atrophied.

Frequently the infant's stomach requires assistance in the assimilation of food, particularly cow's milk. The examination of the gastric contents in weakened gastric conditions has always shown a deficiency in hydrochloric acid. Hence it seems more plausible to give the infant several drops of dilute hydrochloric acid after feeding.

In conclusion permit me to say that two drugs must always be considered in the management of infant feeding, especially the difficult cases: (1) nux vomica; (2) malt.

65 East Ninetieth Street.

A MISTAKE IN THERAPEUTICS.[1]

By EDWARD P. BUFFET, M.D.,

Jersey City, N. J.

This mistake is the over-estimate of the efficiency of drugs in the cure of disease. It is a mistake made by both physician and patient, but more frequently and decidedly by the patient than by the physician.

It is a popular belief that disease is inevitable. There is a superstitious or a fatalistic sentiment widespread that through some unfortunate event the human race became heir to ills innumerable imposed by some malignant power, which should be expected and waited for with as good grace as possible. As a remedy for these unavoidable ailments it is thought, on the other hand, that some benevolent being has hidden away, in various obscure localities, the specific drug which has been specially devised for each particular ill that flesh is heir to. If only this remedy can be found, the demon of disease can be exorcised; if it cannot, bad luck to the patient. The idea that the mischievous germ can be met and destroyed before it has entered the human organism has not yet become a popular one. Neither is it a general belief that the human animal was ever intended, like the wonderful one-hoss shay, to run his allotted course without medical repair until he is actually worn out and the time arrives for him, as the hospital interne says, to "go to pieces" all at once.

It is in consequence of the mistaken impression as to the value and necessity of drugs that they have been and are now accumulating in marvellous proportions. Eighteen thousand preparations of medicines are registered in the National Dispensatory, with the nature and uses of which the patient kindly assumes that the doctor is familiar, and the number is increasing daily with distressing rapidity.

With drugs so numerous, the habit is easily acquired of using them to excess, and ascribing to them undue importance. The patient divides his ailments into two classes, those which are fatal and those which are not. In the treatment of each class he thinks only of the drugs used. They are the visible and tangible weapons upon which he relies. If he recovers, the drugs and the skill of the doctor in their use are supposed to be the efficient cause. If he dies, the drugs and the doctor are held responsible. Undeserved praise is given to both drugs and the doctor when the issue is favorable, undue blame when it is unfavorable. The doctor often allows one to counterbalance the other, and makes no comment. But there is a fact which experience teaches him and which he does not always disclose to the patient. This fact is that some other cause than the drugs used has effected the recovery, when recovery has taken place. This cause he may not himself fairly understand. He knows only that some inherent tendency to recovery helps him along very unexpectedly at times, and very satisfactorily. He finds it convenient, as well as proper, to cover his ignorance as to the precise nature of that which gives him aid, by the Latin phrase, "vis medicatrix naturæ."

It seems hardly necessary to bring arguments to prove to an audience of intelligent and experienced physicians that an overestimate of the value of drugs in the cure of disease and, as a consequence, of the skill of the physician in using them is made by the patient. It is the experience and observation of the doctor which will convince him of the fact, and if he is not already so convinced, words will be useless. It is the evil effect of the popular mistake and its remedy which is the important subject for consideration.

Noah Webster defines a quack as a boastful pretender to medical skill, one who boastfully pretends to knowledge not possessed. Not many regular practitioners are quacks as thus defined. Most are inclined to lament their want of medical knowledge, rather than to boast of their proficiency. But it does sometimes happen that the patient who believes that his recovery has taken place in consequence of the dose selected by his doctor, when recovery was inevitable under any condition, will boast on his doctor's behalf of a knowledge not actually possessed by him. Should the doctor wink at such undue praise by the patient he becomes a quack by proxy or substitution, and here results one of the first evils of the mistake made by the patient. But in addition to the unfortunate position of the practitioner who receives undue credit the mistake opens the door to outside quackery, and gives a start and an imaginary success to every new so-called system of practice which can be concocted in the brains of any medical enthusiast, and to every patent-pill-maker who can combine two or more drugs so as to act as a cathartic without immediate death to the patient. If in nine cases out of ten the patient would recover without the use of a drug in which now the drug gets the credit, of course any quack or nurse when he attempts the cure will get the same credit in the popular estimation as does the educated physician. Also, if the physician allows the mistaken belief as to the importance of the remedy to go uncorrected, he simply places himself in the nine cases out of ten on the level of the quack and the nurse who can and do practise as successfully as himself when the patient is sure of recovery. It is true that in the tenth case, in which knowledge and skill in the careful selection of the drug may save the patient, he outshines his rival the quack, but this is only one case in which he appears to advantage, whereas in all he should be shown to be a superior in knowledge by his superior success in practice.

The next important question is, What is the remedy for the evil? What shall the physician do to outrival his neighbor the quack, who practises so successfully when nature effects the cure? The answer is plain—correct the popular mistake. Let the doctor make known to his patient how often recovery would take place under the same careful hygienic treatment, even if drugs were not used at all. Let him acknowledge the fact, if he believes it to be a fact, that drugs—and doctors, in so far as they rely upon drugs—are getting credit for cures, which does not belong to them. Teach the patient to rely less upon medicine and more upon

[1] Read before the District Medical Society for the County of Hudson, N. J., October 16, 1900.

an adherence to the rules of hygiene. Inform him that an ounce of prevention is worth several pounds of cure, especially when the ounce is the bactericide which destroys the germ before it has invaded the body, and the pounds are the useless drugs deposited in the stomach after the disease has made its onset. Let the doctor ennoble his calling by acting as a teacher rather than a nurse, a professor of medicine rather than a druggist. Let the doctor of the future give more attention to the rules of sanitation, to the dietetic and hygienic treatment of his patient rather than so exclusively to the medicinal, to the diagnosis and prognosis of disease. If he can do no more than inform his patient of the nature of his ailment, and its probable duration and issue, his services will be in great demand. In the performance of these duties he need not fear the competition of the charlatan. If truth is better than error, and it certainly is in the long run, the doctor will finally be reimbursed for any temporary loss he may sustain of either property or prestige.

Forms of Tremor and their Clinical Characters.—R. T. Williamson states that the relation of tremor to voluntary movement enables us to arrange the cases into three groups; but there are other sub-varieties. (1) Tremor occurring during repose of the limb, but ceasing or diminishing on voluntary movement, with attention tremor which ceases when an object is grasped or when the hands are held out. The tremor in paralysis agitans is usually of this form. (2) Tremor occurring only on voluntary movement and ceasing during repose (intention tremor). This is the form of tremor in disseminated sclerosis, even at an advanced stage; but several other forms of tremor, at a very early stage, occur only on voluntary movement. (3) Tremor which occurs during repose, but which is much greater during voluntary movement; as in most cases of marked alcoholic, senile, asthenic, simple, and hysterical tremor, and in several other varieties.—*The Medical Chronicle*, October, 1900.

Spontaneous Gangrene of the Legs in Childbed.—E. Wormser has made a collection of the cases of this complication to the puerperium found in the literature and added one of his own to the number. The etiology of the affection appears to be somewhat complex. In some instances it may be due to direct thrombosis caused by a diseased heart valve with or without a patent foramen ovale, or there may be a primary arterial thrombosis starting at the placental site and extending upward through the common iliacs to the general arterial tree, or there may be widespread obliteration of the venous channels. The possibility of this is harder to understand, since in order to produce complete blocking of the whole collateral circulation in a part so richly vascular as the foot an almost universal venous thrombosis would seem to be required. Possibly the increased coagulability of the blood during the puerperium may deserve consideration, and in some instances resembling Raynaud's disease a nervous element undoubtedly is also concerned. The trouble may start suddenly or require several days to develop, and presents the typical appearance of dry gangrene, though when there is general sepsis and suppuration of the thrombi wet gangrene may result. Pain is acute, but ceases as soon as death of the tissue has taken place; the only treatment is amputation as soon as the line of demarcation is evident.—*Centralblatt für Gynäkologie*, November 3, 1900.

The Pyogenic Origin of Rheumatism and the Rôle of Trauma in its Causation.—Philip Kissinger's views still further complicate the already unsettled condition of the rheumatism question. It is now almost universally admitted that the disease must be infectious in its nature, but as yet apparently no organism for which the claim of specificity can be upheld has been isolated. On the other hand, instances are numerous in which pure cultures of various pus-producing cocci have been obtained from the blood or other fluids of rheumatic patients, and the author seeks to justify his belief that acute articular rheumatism is closely allied to pyæmia by the citation of a large number of such cases. With this idea as a basis the frequent occurrence of rheumatic joint affections after injury is easily comprehensible, for the local damage produces the place of lessened resistance, which is all that is needed to permit the germs to invade the tissues. These may have already gained access to the system through some separate site of suppuration, an angina, etc., or may directly penetrate the injured skin in the neighborhood of the articulation.—*Volkmann's klinische Vorträge*, September, 1900.

Why are Typhoid and Other Fevers Self-Limited?—J. O. Malsbury believes that the law which governs higher animal life, namely, that constant interbreeding results in less vigorous progeny until finally there ceases to be fertility, holds good in the case of lower animal organisms. In typhoid fever it is fair to assume that there is a new production every twenty-four hours, since there is a reasonably regular variation of temperature of about one degree during that time. This specific element or spore reproduces within and of itself, and with each successive reproduction the spores become less vigorous, until finally fertility ends, reproduction ceases, and the active phenomenon—disease in this particular case—is at an end. If a patient be infected with vigorous spores the attack will be malignant, severe, and abrupt, while if the spores of infection be such as would be found after several successive reproductions, the attack would be mild. Cases that increase in malignancy may have been infected with mixed spores, the cross resulting in increased vigor. Repeated interbreeding would of course end in failure to reproduce, but owing to the severity and prolongation of the attack the patient's vitality may end first.—*Indiana Medical Journal*, November, 1900.

The Malignity of Vesicular Mole.—F. La Torre believes that after the expulsion of a mole, if cells possessing the power of proliferation remain in the uterine muscle walls, they may continue to increase, and by their degeneration produce a malignant tumor, a deciduoma. There appears, however, to be a benignant as well as a malignant form of mole, hence, although every patient who has expelled a vesicular mole should be carefully watched, it is well not to remove the uterus until the symptoms characteristic of deciduoma appear.—*La Clinica Ostetrica*, October, 1900.

Prolonged Applications of Ether Compresses in Strangulated Hernia.—M. Fiessenger says that the majority of cases of strangulated hernia, which it used to be supposed absolutely necessitated operation, yield to this simple method of treatment. Not only the author but several other surgeons have obtained a cure by the applications of ether compresses continued from a quarter of an hour to two hours. The gauze or cotton is kept wet with the ether, and at a given moment there will be a sudden reduction, the patient perhaps giving a cry of pain, and then immediately acknowledging great relief. This treatment may be used during the first thirty-six hours, but after that time there is danger of a gangrenous loop of intestine re-entering the abdominal cavity. The ether doubtless acts in a reflex manner by causing vaso-constriction, with consequent subsidence of the congestion of the intestinal loop.—*Bulletin de l'Académie de Médecine*, October 30, 1900.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 Fifth Avenue.

New York, December 8, 1900.

PROPOSED CHANGE IN THE MANAGEMENT OF NEW YORK CITY HOSPITALS.

THE charter revision commission has just published the results of its deliberations. Among the many radical changes suggested in the mode of governing this city is one that intimately concerns the medical profession. The charter revisers have proposed an amendment which, if carried into effect, will entirely alter the present methods of managing the New York City hospitals.

The amendment provides that on February 1, 1902, the control and management of Bellevue Hospital, including its subsidiary hospitals—Gouverneur, Harlem, and Fordham hospitals, and the Emergency Hospital for Women—shall be taken from the Department of Public Charities and be vested in a board of trustees appointed by the Mayor. Should this amendment become law, the city hospitals will be brought under the same system of control as prevails in private hospitals in the majority of the cities of this country and in the city hospitals of Boston and Cincinnati. It may be also remarked that somewhat similar methods of management are in force in the hospitals of London and throughout the large cities of Great Britain generally, and the system—as is the case in the hospitals of Boston and Cincinnati—has on the whole been found to work smoothly and well. There are many solid and substantial reasons to be urged in favor of the charter revisers' recommendation, and it is to be sincerely hoped that so sterling a scheme will not be killed or mutilated at Albany.

For long the administration of Bellevue Hospital and its subsidiary hospitals has not given general satisfaction. The buildings which constitute Bellevue Hospital are sufficient standing evidence of the truth of this statement, to say nothing of the condition of the old frame erection known as Harlem Hospital. The extraordinary and incomprehensible dilatoriness exhibited by the authorities in neglecting to order the removal of patients to the new Gouverneur Hospital —a building which now has been completed for more than a year—is yet another proof that the powers who rule are, to speak mildly, lax in the discharge of their duties. The greatest gain, however, that the proposed change would bring to those who are compelled to have recourse to the city hospitals for medical treatment would be the removal of these institutions from the domain of politics. Indeed it is mainly owing to the part that politics has played in the management of the city hospitals that their services have not been so efficient as the citizens of New York had a right to expect they would be.

No person of ordinary reasoning powers can disagree with the plain proposition that politics should have no place in the management of an institution set apart for the care of the sick. The trail of the serpent of politics may be traced in the administration of all the public affairs of New York, but it should be surely worth while to make a strenuous effort to remove charitable institutions at least from such contaminating influences. Another reason (given in an article on the matter which appeared in the Sunday *Sun*, December 2d, demonstrating that Bellevue would be a gainer by the proposed amendment) is that it would be thereby made a specific city interest, independent of the other institutions in the Department of Public Charities. As *The Sun* says:

"The patients in Bellevue are by no means all paupers; they are for the most part workingmen and workingwomen who, by reason of illness or injury, are temporarily prevented from earning a living. They cannot afford medical care and nursing at their homes, and go to their only place of refuge—the public hospital. And it is only the part of a wise policy on the part of the city to make them well and again self-supporting as soon as possible. It is not just, it is not humane to class them with paupers and thus rob them of their self-respect. Bellevue has too long been considered in the public mind as a pauper's hospital. Let us hope that this stigma will be removed under the new form of administration."

There can be no doubt that a stable, steady form of government, entirely divorced from politics, would accomplish great things for the New York City hospitals. That amendment proposed by the charter revision, therefore, deserves the good wishes and support of the medical profession and the general public.

SMALLPOX AND VACCINATION.

THE outbreak of smallpox on the West Side of this city, although so far not especially alarming, will doubtless tend to impress upon the minds of its inhabitants the need of vaccination and revaccination. Indeed, if it has this effect, the activity of the disease—restricted though it be—will prove a "blessing in disguise." It speaks volumes for the intelligence of the American people as a whole, and of this State in particular, that there has never been evidence of an organized opposition to vaccination. Among a minority of the inhabitants of the United States a certain prejudice against vaccination exists, but with the bulk of the population the sentiment with regard to the operation is one of apathy, or rather of indifference. It is so long since an epidemic of smallpox on a large scale and in a virulent form appeared in this part of the country that many persons are sceptical as to the dangers to be feared from such an occurrence. Without wishing in any way to act the part of alarmists, we

would nevertheless sound a note of warning, and advise parents not to be lulled into a state of false security. The fact that as a community we are well protected cannot be denied, but if the practice of vaccination be allowed to fall into disuse it is impossible to say for how long this happy condition of affairs will last. A few apropos truths concerning the benefits conferred by vaccination may at the present time be of interest. The following statistics are culled from an able article on the subject written by Dr. C. D. Smith, president of the board of health of the State of Maine: The German law of 1874 makes vaccination obligatory in the first year of life, and also revaccination obligatory at the tenth year. This law in Germany resulted from the epidemic of 1871, with its one hundred and forty-three thousand deaths, among a population in which vaccination had been allowed to die out. Prior to 1874 the yearly loss was fifteen thousand to twenty thousand. The present rate is less than one hundred and sixteen per year, and these cases occur on her borders, where there is constant mingling with the poorly vaccinated of other countries. The disease does not spread or become epidemic among well-vaccinated people. It does so develop among the unvaccinated. During the Franco-German war the inevitable mingling of the two peoples spread smallpox, which was epidemic. The Germans had made vaccination optional for its civil population, but compulsory for its army; the French having made it optional alike for army and population. The French lost from smallpox twenty-three thousand men; the Germans two hundred and seventy-eight. Occupying the same hospital tents, with the same surroundings, the French wounded lost many from smallpox; the Germans, not any. The French prisoners of war died by the hundreds; their German guards, who had been vaccinated and revaccinated, suffered not at all. In Denmark, Sweden, and Norway, where, as well as in Germany, vaccination is compulsory, the annual death rate is from one to three per million. In England and Wales, before the introduction of vaccination, the mortality was three thousand per million; since the introduction of vaccination it has been reduced seventy-five per cent. From the time that statistics were first collected, facts confirming the ravages of the disease in unvaccinated communities have been unvarying, and the reduction of its prevalence and of the death rate after vaccination has received equal confirmation. Among savage races and in other unprotected communities smallpox invariably attacks almost all who are exposed to its infection. When a partially protected community is attacked the victims selected are the unvaccinated. This has been demonstrated over and over again on this continent among the North American Indians and in Mexico, where in both instances the populations of entire villages were completely wiped out. Observation has also shown that when the vaccinated are attacked by smallpox the disease is in them in a modified form. The contention is not made that vaccination is an absolute preventive, but it is asserted that it modifies and controls the disease to a very considerable extent. The great majority are protected by vaccination, and with those affected the danger to life and disfiguring marks are avoided. In short, vaccination changes the whole course of the malady. Much of the prejudice that undoubtedly exists against vaccination is due to the fear that by the use of unclean lymph, or by the performance of the operation in a careless manner, certain diseases may be transmitted to the person operated upon. In times gone by this dread was sometimes warranted, but at the present time, by special preparation and storage, the lymph is rendered practically harmless, and provided that the operator is careful and practises aseptic methods no ill effects are likely to result. Revaccination should be undergone at the age of puberty, and as a measure of precaution in those places where smallpox is prevalent. The health authorities in this city are taking energetic steps to check the spread of the disease and may be depended upon to succeed in their object, but at the same time we would advise every one who is in a fit state of health to be revaccinated. Especially is it incumbent upon parents in the interest of public health to order their young children to be vaccinated.

THE PURIFICATION OF THE NEW YORK WATER SUPPLY.

On Friday last the grand jury finished the taking of evidence with regard to the New York water supply, and handed the conclusions at which it had arrived in written form to the recorder. Respecting the quality of the water the grand jury took the following common-sense view: "While in no way detracting from the importance of a pure water supply, as a condition necessary to the public health, the grand jury was relieved by the preponderance of testimony to the effect that no immediate danger of typhoid existed or was imminent, although it was conceded that a long continuance of an impregnated water supply would be liable to produce disease. The conclusions, after careful consideration of the subject, are that the only effective and permanent means by which a remedy can be applied to existing evils, and the only means to secure pure water, consist in the adoption of a system of filtration commensurate in all respects to the needs and wants of this great municipality." As was pointed out in the Medical Record of December 1st, the primary outlay will be great, but the establishment of a thoroughly efficient filtration system on a scale sufficiently large to comprehend the entire water supply of Greater New York is a public necessity, and the cost in the end will be money well spent. The reduction of the mortality rate from typhoid fever alone is adequate cause for advocating its adoption. In London, in Hamburg, and in other European cities too numerous to mention, this fact has been so strongly emphasized as to admit of no dispute. In this country also there already have been some conspicuous examples of the benefits conferred upon a community by ridding the drinking-water of noxious germs. For instance Lawrence, Mass., was up to the time of the establishment of a filtration plant a hotbed of typhoid fever. From 1887 to 1892 inclusive,

the number of deaths from typhoid in that city ranged from forty-seven to sixty per annum, a rate per ten thousand population of 11.44 to 13.44. The filter plant was put in operation in the latter part of 1893, and the typhoid deaths for that year fell to a total of thirty-nine and a rate of 7.96 per ten thousand. In 1894, the first full year the filter was in service, the deaths were twenty-four and the rate 4.75 per ten thousand. There has been a steady diminution ever since, until in 1898 there were but eight deaths from typhoid fever in the city, giving a rate of 1.39 per ten thousand population. Albany is another case in point. The evidence in favor of a filtration system is so overwhelming as to be conclusive. The city of New York in almost every respect has good reason to be proud of her water supply. Compared with London and Paris it is bountiful in the extreme. The deficiency of London's supply will be clearly apparent when it is contrasted with that of some European cities and with nearly all American cities of any size. London doles out on the average about thirty gallons per head daily. Rome and Naples are generous with water by comparison, Vienna is lavish, while Washington gives each inhabitant one hundred and fifty-five gallons per day, Chicago one hundred and nineteen gallons, and New York one hundred gallons. Paris, of all the civilized cities of the world, is the only one which is content with London's low level. Although we must confess with shame that no city of the modern world can equal ancient Rome, which gave to each citizen on the average two hundred and thirty gallons of water a day, carried at an enormous cost from the mountains through aqueducts which are at once the admiration and despair of present-day engineers, yet the cities of the United States are, so far as the quantity of water supplied is concerned, the nearest rival to the erstwhile mistress of the world. Where our cities fail is in the quality of the water supplied, and hence the great prevalence of typhoid fever throughout the country. The redeeming feature of London and other British centres of population is that the water supply is rendered by artificial means as pure as possible, and in consequence of these precautions typhoid fever has been almost stamped out. Many American cities are recognizing, though somewhat tardily, that efficient filtration of water is one if not the most important safeguard to the health of their dwellers. Philadelphia, Washington, Cincinnati, Pittsburg, Louisville, and Atlanta are busily engaged in constructing filtration plants, and New York in her care for the welfare of her citizens will undoubtedly follow suit. An abundance of water is an absolute need for every city in order to be clean, healthy, and pleasing to the eye. There should be not only an ample supply of water on tap in our houses, but enough to water the streets, flush the drains, and indeed for all sanitary purposes; and, in addition, in the hot weather plenty of fountains should be continually running, both for drinking and for imparting that sense of coolness and rest so necessary to those who are compelled to pass their lives within the confines of a town. The quality of the water should be beyond reproach, and the quantity should be adequate for domestic supplies as well as sufficient to give an unstinted amount for municipal purposes. There is no reason that New York should not be in this ideal position as regards water. It is certain that by adopting a filtration system, founded upon the best models now in use, she will be making a long stride in this direction.

ARSENIC POISONING BY BEER IN ENGLAND.

In Great Britain of late arsenic has come to the front in a very unpleasant manner. It is not very long since that a prominent firm of wholesale druggists sent out a large quantity of effervescing salts, into which, through some grave error, arsenic had been introduced. Before the mistake could be rectified by calling in the pernicious salts several persons had suffered severely from imbibing the so-called cooling beverage. A short time ago it was found by individuals who drank beer brewed by some Manchester firms, that extremely deleterious results followed. Upon investigation the discovery was made that arsenic had obtained an entrance into the beer, although it must be said that it was present only in a beer of special brew. The brewers themselves assert that the products of only one firm have been harmful, and that arsenic was introduced through improper treatment of sulphuric acid in brands of sugar coming from Spain. Others aver that the mischief has been due to a particularly bad lot of glucose supplied to Manchester and Liverpool brewers, which caused peripheral neuritis very similar to beriberi. Be this as it may, one fact at least stands out with sinister prominence. There have already been over a thousand patients and nearly seventy deaths owing to the consumption of this ill-omened beverage. The news is also reported that this beer-poisoning epidemic has spread to London, and that the county council intends to take up active measures to protect the community. The *New York Tribune* (Sunday, December 2d) states that the British workman now empties his pewter pint with more or less fear and trembling, and analysts are busy by day and by night on samples of the glucose and saccharin used extensively by brewers. A curious suggestion is made by an English public analyst, in connection with this matter, that the Maybrick case might have been solved had the facts now made public in regard to arsenic in beer been known at the time of the trial.

Widal Examinations at Quarantine.—Dr. Alvah H. Doty, health officer of the port of New York, announces that the Widal test for typhoid fever will be made free of charge in the laboratory of the quarantine station at the request of any physician in New York State. The material and full directions for securing and forwarding the blood or serum to the department for examination will be sent on application, and the result of the examination will be promptly communicated to the sender. These examinations are intended to put this important diagnostic aid within the reach of physicians in the country and in small towns where no bacteriological laboratories exist.

News of the Week.

The Late Prof. Henry D. Noyes, M.D. — At a meeting of the medical staff of the New York Eye and Ear Infirmary the following recognition of the services of the late Dr. Noyes was duly entered upon the minutes:

Dr. Henry D. Noyes was a graduate of the College of Physicians and Surgeons in the year 1855. After serving on the house staff of the New York Hospital, he went to Europe to continue his studies. Having devoted himself to special work in the ophthalmic clinics there, and latterly having been a student of von Graefe in Berlin, he returned to America, and in September, 1859, was appointed an assistant surgeon to this infirmary. In November, 1864, he was made surgeon. From 1873 until 1898 he served as executive surgeon, and on October 23, 1900, his resignation as a member of the surgical staff was received by the board of directors—by the board at whose councils he had sat for a period of thirty-six years.

This long service of one who during nearly the entire time held foremost position in conducting the affairs of the institution covers more than half the period that has elapsed since the foundation of the infirmary. These years have seen marked changes in the growth of the institution, and a brief reference to the statistics furnished by our annual reports may not be out of place.

In the year 1859 there were 4,178 new dispensary patients and 144 in the wards. In 1899 there were 47,684 new dispensary and 2,257 house patients. In 1859 the surgical staff consisted of nine men. Now, eighty-three medical men are engaged in the work. In 1859 it was an eye infirmary. Now, there are the three departments of the eye, ear, and throat.

The well-ordered hospital of to-day, with its superintendent and clerks, its isolated cataract wards and pavilion for contagious ophthalmia, its training-school for nurses, school of instruction for graduates of medicine, its annual volume of scientific transactions, its valuable medical library, owes in no small way its pre-eminence to the wise forethought and ceaseless activity of Dr. Noyes.

The rules and regulations of the infirmary were largely the result of his careful study, and it was perhaps characteristic of his unselfish devotion to the institution that, shortly before his resignation of the position of executive surgeon, he prepared rules that gave this office largely increased powers and left the enjoyment of them to his successor.

Bringing as he did to the discharge of his professional duties a vast knowledge of medicine, a facility and originality in operative procedure, he was unsparing of self in his devotion to those who came under his care. He was prompt in recognizing the value of suggestions made by others in his field of work, and his distinguished position as an author and teacher added to the fame of the institution both at home and abroad.

Throughout the years of his connection with the infirmary Dr. Noyes contended for an increase in our scientific and laboratory work. He urged that there could be no effective and perfectly developed charity that was not associated with scientific investigation.

Dr. Noyes died on the 12th of November, 1900. It is fitting that the medical staff of this institution, to the service of which he had devoted all the years of his active professional life, should record their appreciation of the work of a man who has contributed so largely to make the infirmary what it is. It is proper that at this time, feeling the irreparable loss they have sustained in his death, they should, in the spirit in which he lived, dedicate themselves anew to its service, not alone as ministers to humanity, but also as ministers to knowledge in medicine.

A Meeting of the New York State Medical Alliance will be held at the New York Academy of Medicine, 17 West Forty-third Street, Thursday, December 13th, at 8 P.M. Dr. Winfield S. Hall, A.M., M.D., Ph.D. (Leipzig), professor of physiology, Northwestern University Medical School, Chicago, will read a paper on "Ethyl Alcohol: its Biology and its Relation to Physiology, to Pharmacology, and to Therapeutics." Discussion of the paper is expected by Professor Conn, of Wesleyan University; Prof. C. A. Herter, of the University and Bellevue Medical School; Professor Woodbury, of the Philadelphia Polyclinic and College for Graduates, formerly professor of materia medica and therapeutics in the Medico-Chirurgical College of Philadelphia, and by others. Dr. Andrew H. Smith, president of the alliance, will preside. The medical profession is invited.

A Suit against Physicians.—A malpractice suit for $60,000 damages, brought against Drs. Manges and Rosenberg of this city, has resulted in a disagreement of the jury, the division being nine to three in favor of the physicians. The suit arose from a curettage, in 1897, to check severe hemorrhage in a woman with large fibroid tumors of the uterus. It was claimed that the operation was performed without consent, that it was unskilfully done, that too much chloroform was administered, that there was neglect in the after-treatment, and that the woman had no fibroids. The basis for the claim that there were no fibroids was the naive statement that there was no external protuberance of any kind.

The Class of '90 of the College of Physicians and Surgeons.—On November 15th a dinner was given at the New York Athletic Club to commemorate the first decennial anniversary of the class of '90 of the College of Physicians and Surgeons of New York. Forty-nine members of the class were present, and speeches were made on the following topics, Dr. H. Beattie Brown acting as toast-master: "The Class," by Dr. James Pedersen; "Our College," by Dr. Charles W. Townsend; "A Retrospect and Historical Report of the Class," by Dr. A. Ernest Gallant; "The Decennial Dinner," by Dr. W. Whitehead Gilfillan; "Clinical Medicine," by Dr. A. W. Hollis; "Modern Surgery," by Dr. Percival Bolton; "Medical Testimony," by Dr. Charles I. Proben; "Commercialism

in Medicine," by Dr. Henry P. De Forest; "What Measure of Success Should a Physician Achieve in Ten Years' Practice?" by Dr. Henry L. Palmer; "The Physician in the Country," by Dr. Charles F. Chapman; "Town vs. Country Practice," by Dr. Sidney A. Twinch; "Philanthropic Work of the Physician," by Dr. Edward W. Peet; "Requirements necessary for Success in Our Profession," by Dr. Henry H. Forbes. Impromptu toasts were responded to by Drs. Arthur B. Coleburn and Henry F. Adams. The next reunion will be five years hence. The following officers were elected: *President*, Dr. James F. McKernon; *Secretary*, Dr. A. Ernest Gallant; *Treasurer*, Dr. William Whitehead Gilfillan.

Smallpox in New York.—A nest of smallpox patients was discovered last week by the board of health in West Sixty-ninth Street. Between thirty and forty patients were found and removed to hospital. The result of the discovery and its publication in the papers has been a vaccination boom of no mean proportions.

Dr. Ramiro Diaz, a gradnate of Vanderbilt University, Nashville, in 1894, has been appointed to the medical corps of the Mexican army and navy, with the rank of captain (capitan 1°). There is in Mexico a special military medical school, from which Dr. Diaz was graduated after completing his studies in this country.

Typhoid Fever has been unusually prevalent in New York this autumn, but the number of cases is now diminishing rapidly, as it always does in the late autumn. The number of cases reported in each week for the period beginning with the week which began on September 2d and extending to the week which ended November 24th, is as follows: 88, 116, 83, 129, 104, 139, 88, 140 (week ending October 27th), 105, 90, 86, 79. The deaths from the fever in the corresponding weeks last year were as follows: 27, 28, 22, 20, 15, 27, 16, 32 (week of October 27th), 28, 27, 17, 22.

The State Hospital for the Treatment of Tuberculosis.—The trustees of the State tuberculosis hospital have presented their report concerning the site to the State board of health. The report relates that after the consideration of the sites offered, the one at the west end of Lake Clear in Franklin county was selected. Protests against the site were made at a public hearing, and no decision has yet been made by the boards of approval. It is believed that the necessary ground can be purchased for $10,000 to $12,000, and the estimated cost of construction and equipment of the hospital is $200,000. The plans for the buildings are now being prepared by the State architect.

Gifts to the Chicago College of Physicians and Surgeons.—Fifty thousand dollars has been given to the College of Physicians and Surgeons, of Chicago, for endowment purposes by two members of the faculty. Dr. William E. Quine, dean of the school, gives $25,000 to endow the college library, and Dr. D. A. K. Steele gives $25,000 to endow the pathological laboratory. The gifts are conditional upon the purchase by the trustees of the University of Illinois, of which the College of Physicians and Surgeons is a part, of a building suitable for the library and the laboratory. The income from Dr. Quine's gift will be devoted to the purchase of books.

Arrest of a Swindler.—A man who gave his name as Dr. Ferguson, of Galveston, was arrested in this city a few days ago on a complaint by Dr. Jarman that Ferguson had swindled him out of a small sum of money. When the man was brought into court the detective showed to the magistrate a copy of the Medical Record containing a warning sent out to all physicians by a Dr. W. Peyre Porcher, of Charleston, S. C., against a swindler impersonating himself and pretending to have attended the Congress of American Physicians and Surgeons in Washington and to have lost all his money. The description of the man tallied exactly with that of Ferguson. Later he was positively identified by Dr. Shands, of Washington, as the man who had represented himself to be Dr. Porcher.

Philadelphia Neurological Society.—At a stated meeting held November 26th Dr. F. Savary Pearce exhibited "A Case of Brachial Monoplegia of Traumatic Origin." On account of the total helplessness of the affected member the wisdom of amputation was considered, but the consensus of opinion was against such a radical operation, although a year had elapsed since the causative accident, and no improvement had resulted from treatment. It was thought better rather to expose the brachial plexus and determine its condition, at the same time remedying any gross deficiencies that might be found and persisting subsequently in massage and electricity. Dr. Charles K. Mills exhibited "A Case of Associated Tabes and Disseminated Sclerosis." The patient was an old man who presented abolition of the knee jerks, Argyll-Robertson pupil, tremor of the head and of the hands on intended movement, with good station and steady gait. Dr. Mills exhibited also "A Case of Pseudo-bulbar Paralysis," apparently due to lesions of both cerebral hemispheres and attended with profound emotional mobility, bilateral paresis more marked upon one side, and increased knee jerks, without trophic changes. Dr. F. X. Dercum exhibited "A Case of Myopathy," in which there was wasting of the muscles of the face and of the upper extremities, with increased bulk of the calves. Dr. Dercum exhibited also "A Case of Obscure Diagnosis," occurring in an adult male in whom there had been pain and tenderness in the course of nerves, followed by paraplegia and increased knee jerks, with wasting of the scapular muscles. Dr. A. R. Allen exhibited "A Case of Partial Ophthalmoplegia," with exophthalmos, in a man in whom only the fourth nerve seemed to be intact. The opinion was expressed that the condition was dependent upon an orbital new growth. Dr. D. J. McCarthy exhibited "A Case of Polyneuritis of all Four Extremities, Passing into the Duchenne-Erb Type of Brachial-plexus Palsy," occurring in a young typesetter, who

had exhibited a blue line on the gums and other symptoms of lead poisoning and had been addicted to alcoholic excess. The wasting in the muscles of the shoulder girdle and of the upper extremities was extreme, and suggested possible invasion also of the ganglion cells of the anterior horns of the spinal cord. Dr. W. G. Spiller reported "A Case Presenting Symptoms of Cerebro-spinal Meningitis with Intense and General Alterations in the Nerve Cells, and Little Evidence of Inflammation," occurring in a feeble-minded child in whom death had occurred suddenly in the course of an acute illness.

The Charles K. Mills Neurological Society listened on November 19th to an address on medicine delivered by Dr. S. Weir Mitchell.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the navy for the week ending December 1, 1900. November 23d.—Assistant Surgeon C. R. Burr ordered to the *Monongahela*, December 1st. Assistant Surgeon R. K. McClanahan detached from the navy yard, Washington, and ordered to the *Indiana*, December 1st. November 27th.—Passed Assistant Surgeon R. Spear detached from the naval hospital, New York, and ordered to the *Buffalo*, December 5th. Assistant Surgeon R. B. Williams ordered to duty at the naval hospital, New York, December 5th.

Philadelphia County Medical Society. — At a stated meeting held November 28th Dr. Jay F. Schamberg read a paper entitled "Refractory Cutaneous Syphilis, with Report of a Case and Exhibition of the Patient." He cited instances of undoubted syphilis in which the symptoms declined to yield to the employment of mercurials and iodides in varied form, mode of administration, and dosage. Dr. Edward Martin presented a communication on "The Treatment of Gonorrhœa." For acute anterior urethritis he recommended injections of protargol and potassium permanganate in solution, for posterior urethritis the employment of irrigation, and for chronic urethritis local applications. Dr. John G. Clark made a communication on "Cystoscopy in Women," with a demonstration of instruments. He expressed a preference for the Nitze-Leiter cystoscope for diagnostic purposes, and for the Kelly cystoscope for therapeutic purposes. The latter has the disadvantage of requiring the knee-chest position, while the former requires only the lithotomy posture. A resolution was adopted petitioning the board of education to make an appropriation of $500 for each of a sufficient number (one or two hundred) of medical inspectors to carry out successfully and continuously the work of daily inspecting children in the public schools presenting symptoms of illness, and sending home those found to be sick. The work has been done gratuitously for nearly a year by a volunteer staff of physicians, with the result of preventing a good deal of contagious disease among the children and their families, and ameliorating the severity of attacks of disease through early diagnosis and confinement at home.

Obituary.

RUFUS P. LINCOLN, M.D.,

NEW YORK.

Dr. Rufus P. Lincoln, aged fifty-nine years, died November 27th at his home in this city, after an operation for appendicitis, performed ten days ago. The immediate cause of death is said to have been septic peritonitis. Dr. Lincoln was born in Belchertown, Mass., in April, 1841. He received his early education at Wiliston Seminary and was graduated from Amherst College in 1862. He then entered the army as a second lieutenant in the Thirty-seventh Massachusetts, and served until the close of the war, coming out colonel of the Thirty-seventh. He was wounded at the Wilderness and again at Spottsylvania. He began the study of medicine in New York at the College of Physicians and Surgeons, but after a year went to Harvard and obtained his medical degree there in 1868. After serving as interne in the Massachusetts General Hospital in Boston he returned to New York and entered upon the practice of his specialty, namely, that of laryngology, in which he soon won deserved distinction. He was one of the earliest physicians to apply electric cautery to throat operations, and his removal of a tumor from the throat of Gen. Judson Kilpatrick by this means was considered at the time quite remarkable. Dr. Lincoln was married in 1869. His wife, who was a Miss Tyler, of Pittsfield, Mass., and one daughter survive him. Dr. Lincoln was a member of the Loyal Legion, the University Club, Amherst College Club, and the American Laryngological Society.

Obituary Notes.—Dr. A. L. A. Toboldt died at Philadelphia on November 23d in uræmic convulsions at the age of forty years. He was born in Germany, came to this country as a child, and was graduated from the medical department of the University of Pennsylvania in 1880. He had been demonstrator of materia medica in the university.

Dr. Walker R. Stephen died at Reading, Pa., on November 27th, at the age of forty-nine years. He was a graduate of the medical department of the University of Pennsylvania.

Dr. Clarence E. Foster died on November 26th at Honesdale, Pa., at the age of forty-three years. He was coroner of Wayne county.

Progress of Medical Science.

Medical News, December 1, 1900.

A New Operation for Hemorrhoids.—Ellsworth Eliot states that the following procedure, which has been tried during the past six months in the Presbyterian Hospital of New York, has given excellent results in a number of cases: After the customary preparation and with the usual precaution of as perfect cleanliness as is possible under the circumstances, an anæsthetic is administered, and the sphincter having been stretched the hemorrhoids are allowed to protrude. Each advanced hemorrhoidal area is treated similarly as follows: Opposite the base of the hemorrhoid, parallel with and corresponding to the mucocutaneous junction, a curved incision is made and carried upward in the same plane as in a Whitehead operation beneath the pile-bearing area until the base of the hemorrhoid is reached. A second curved incision is then made in and through the mucous membrane, forming an ellipse with the first-mentioned incision and including within this ellipse any area of ulceration at the base of the hemorrhoid that may have developed as a result of the irritation to which the exposed surface of the mucous membrane overlying the hemorrhoid is subjected. From the junction of the two curved incisions an incision is carried vertically upward through the mucous membrane only, and the re-

sulting quadrangular flap of mucous membrane is reflected from the surface of the underlying hemorrhoidal area, having its base of blood-supply superiorly. After the dissection of this flap, the same vertical incision is deepened through the hemorrhoidal tissue proper, forming a rectangular mass of hemorrhoidal tissue which is transfixed at its base with stout catgut: the ligatures are then tied tightly and the mass is removed. The rectangular flap is stitched to the skin and the retention of any discharge prevented by cutting the catgut ligature long and allowing the ends to protrude below, thus acting as a drain. This same procedure is repeated in not more than two other places where the hemorrhoids are most pronounced. A dressing of sterile gauze is placed over the suture line, a large tube, surrounded by iodoform gauze, having been previously introduced into the lumen of the gut. Prompt union is generally secured and the complete excision of all areas of ulceration at the base of the hemorrhoid is attained.

The Treatment of Pneumonia with Anti-Pneumococcic Serum.—Edwin Rosenthal writes that, clinically, pneumonia is met with as croupous pneumonia, a self-limited disease which should end favorably, and catarrhal pneumonia which has no limitation. A very great and essential factor in all histories of catarrhal pneumonia is told in the word—complication. When pneumonia comes as a complication or sequel to other diseases, the antipneumococcic serum can be used at once, and the addition of the antistreptococcic serum is as needful. The method of administering the serum is by hypodermic injection into the tissues of the body. The indications for its use are as follows: The temperature, pulse, and respiration should be taken as a guide, and the severity of these symptoms governs the method and size of dose and its repetition. If, for instance, the temperature be 103° F. or over, the pulse 140 or over, and the respiration 48 or over, the writer begins with 20 c.c.; when the type is more severe, with 40 c.c. of the serum, followed every four hours by double the initial injection, until the disease is under control, as manifested by a decline of temperature, a slower respiration, disappearance of pain, improvement in the pulse, and a change for the better in the general condition. If the case be croupous, the first twenty-four or forty-eight hours show the effect of the remedy. When the pneumonia is secondary to another disease, the antipneumococcic serum should be followed in four hours by an injection of antistreptococcic serum. The use of serum does not interfere with other treatment, nor is it harmful in any quantity, at any stage of the disease. At the same time the familiar suitable remedies should be employed. None of the foreign serums is reliable. It is not the one dose or the one bottle that will cure, but sufficient quantities must be used till results are obtained, whatever that amount may be.

The Influence of Measles and Erysipelas upon Epilepsy, with Report of Cases.—L. Pierce Clark and E. A. Sharp draw the following deductions from the study of their cases: In not one instance was the pre-existing epilepsy favorably modified for any great length of time. In a few cases the progress of the disease was accelerated by the infectious complication, and in one the measles caused status epilepticus. In those cases in which the epilepsy was favorably modified, the temporary improvement was slight and of very short duration. They therefore conclude that instead of the physician urging his patient to run the risk of an infectious disease, with the small chances of such an accident resulting favorably to the existing neurosis, he should urge them to avoid any and all such complications as far as possible.

A Case of Multiple Aneurisms.—By W. J. Pettus. The patient was a man of forty-one who died a month after admission to hospital. The autopsy showed the following condition. The whole extent of the innominate artery was involved in a fusiform aneurism extending up to and including the first and second parts of the subclavian. This aneurismal sac was about two inches in diameter, and also involved the right common carotid. A great effort at a cure had been made, especially in the innominate portion of the aneurism. There a firmly organized clot filled the sac, except where a small channel for the blood was left. The sac of the subclavian, too, was filled with partly organized clot, leaving a very narrow channel for the blood current. There was also found a fusiform aneurism of almost the entire abdominal aorta, beginning at and including the cœliac axis and extending down to the third lumbar vertebra, just below the origin of the inferior mesenteric artery. The bodies of the last dorsal and the first, second, and third lumbar vertebræ were eroded by the aneurism, to the depth of half an inch, the intervertebral substances being intact. At the origin of the cœliac axis the sac had ruptured on the right side, and the blood had burrowed behind the peritoneum, forming an immense clot, amounting to half a gallon of blood, extending from the diaphragm to the crest of the ilium on the right side. The liver was pushed upward and forward by the large clot. From the history given the abdominal aneurism must have ruptured a week before the patient came under observation.

Report of a Case of Empyema of the Antrum of Highmore of Fifteen Years' Duration, Due to a Foreign Body; Operation; Recovery.—The patient in the case reported by A. B. Duel was a woman of thirty. The symptoms had been of the type usual in empyema of the antrum. Several openings had been made into the cavity and syringings carried out but with no permanent relief. Duel opened through the canine fossa and on exploring with the finger found a calculus made up largely of inspissated mucus around a nucleus, consisting of the fang of a molar tooth which had been forced into the antrum by a dental operation fifteen years before. Curetting, packing, etc., were done, the latter being repeated daily for four days when a large rubber tube was substituted. The discharge stopped in a week. The tube was removed in three weeks. The patient has remained well for eighteen months.

Practical Medicine and Laboratory Research.—Beverley Robinson utters a protest against the unreserved acceptance of the germ theory of disease causation. We are to take into account all the information the laboratory can furnish but should not attach undue weight to evidence from this quarter. Concerning laboratory reports Robinson says that he has had more than once been sceptical as to the time, care, skill, and knowledge employed in making them. He feels that in any important case the knowledge and technique of the observer must be above cavil. Behind the disease is the patient and this fact should always be borne in mind. The clinician must rank foremost and to him the chemist and bacteriologist should always report their findings. It is he who should settle the importance they have and the treatment, prophylactic and curative, which should be adopted.

A Contribution to the Therapeutics of Phlegmasia Alba Dolens.—A. Herzfeld has used in one case the unguentum Credé. The interestiug features of this case are the comparatively late appearance of the phlegmasia alba dolens (on the twentieth day after delivery) and the rapid effect of unguentum Credé on pain, fever, aud swelling, after all other means had signally failed, leading to the impression that its action was very similar to that of antitoxin. Herzfeld calls special attention to the large dosage used (15 gm.), which he considers necessary for an effective use of the remedy.

Journal of the American Medical Ass'n, Dec. 1, 1900.

Bacteriological Examinations of Otitis Media Purulenta and Suppurative Mastoiditis.—This report is made by Talbot R. Chambers. At the beginning of the autumn, 1899, the rule was adopted that whenever an otitis purulenta, acute or chronic, came under treatment, the canal was to be thoroughly cleansed with hydrogen peroxide, and granulations and polyps were to receive appropriate treatment tending to their speedy removal if possible. The same order was then given in every case, viz., hot-water syringing to be followed by instillation of enzymol in the canal. If after one week no improvement was noted, the enzymol was discontinued, and the hot-water syringing was changed to hot bichloride (1:4,000), or hot carbolic acid (10 to 20 drops to the pint), or hot Seiler's solution. The water was at 120° F. When the auditory canal was swollen and the mastoid painful, leeches were applied in the early stage and then six hours later, after the bleeding had stopped, the following treatment was employed every hour for twenty-four or forty-eight hours: Ten minutes' syringing with hot water at 120 F., ice poultice bound firmly on for fifteen minutes, and a continuous application of a hot-water bag for the

remainder of the hour. The writer believes that the abortion of twenty-eight out of thirty-nine cases of acute mastoid inflammation, presenting swollen auditory canal and mastoid pain, is due to this treatment. In no acute mastoid case when this treatment was properly carried out was operation done. In a number of cases paracentesis of the drum membrane was performed one or more times. Tonic constitutional and hygienic measures suitable to the individual were in all cases taken. The writer emphasizes the fact that the great value of a microscopical examination of the catarrhal or purulent discharge is seen in the case of diplococcus pneumoniæ (Fraenkel), in which a speedy cure may be prophesied, and one may with equal confidence sew up the mastoid wound completely and discharge the patient in about one week, or at most not over two weeks; with streptococcus alone, fifty per cent. are cured. One case of acute suppurative mastoiditis (streptococcus alone) had hot-water syringing and zinc chloride instillation of two per cent. strength, and after paracentesis came to rest in two weeks. With streptococcus and pyocyaneus the chances are even of an eventual if tardy cure. With streptococcus and staphylococcus the chances are two to one against cure. If staphylococcus alone be present, four out of nine may come to a cure. If pyocyaneus exist alone, one-half may be cured and the others prove stubborn. If coli bacillus communis be the germ the case is practically incurable. All these cases may prove stubborn except the diplococcus pneumoniæ (Fraenkel), which yields forthwith to pepsin.

Boston Medical and Surgical Journal, Nov. 29, 1900.

Subperiosteal Fractures.—Frederick J. Cotton reports a number of cases of this class of fractures, which is very common among children, and a large proportion of which seem on close examination to have little in common with the type known as green-stick fracture, with which they are usually classed. Here there is no deformity, because there are no torn surfaces, but a clean-cut crack or cross fracture, and no bent or half-broken layer of bone to prevent the motion necessary to readjustment of the surfaces. The lack of crepitus and mobility seems to be largely or entirely dependent on the strength of the thick intact periosteal layer. From cases observed and experiments tried, it would seem that blows are less likely than a more slowly acting strain to produce typical green-stick fractures. It seems that fractures in children showing no deformity and no appreciable mobility are not uncommon; that they might readily be overlooked; that they often need no reduction, having no deformity; that they often repair with callus, and quickly.

Irritable Breasts, or Chronic Lobular Mastitis.—R. C. Cabot reports two cases of lump in the breast in two young unmarried women. The lumps were painful to the touch. They are improving under treatment addressed to general debility and anæmia. The author queries whether these tumors may possibly be galactocele (of which several cases are on record in unmarried women), or whether it may not be that the lumps are physiological, and that a considerable number of women have them and do not find them out. He also seeks information as to the prognosis, and the treatment.

Cysts of the Vocal Cord.—By J. Payson Clark.

The Philadelphia Medical Journal, December 1, 1900.

On the Treatment of Tuberculosis by Sodium Cinnamate.—Alfred Mann states that there are two important characteristics in which tuberculosis differs from the acute infectious diseases, such as diphtheria and pneumonia: 1. It tends to the production of marked and permanent anatomical changes in the organs and tissues involved. 2. It causes little or no immunizing reaction in the organism. The most successful modes of treatment in the past, excluding surgical measures, have been those that aimed to improve the general health of the system, those that relied upon the natural tendency of the body to resist and expel infection and that in any way, directly or indirectly, increased its defensive powers. Among the chief of these are the out-door and climatic treatment, the dietetic and hygienic methods, and the treatment in sanatoria. The writer then gives his experience in the use of sodium cinnamate or hetol. He has employed the method of intravenous injection of solutions of this drug, following very closely the directions given by Professor Landerer. Beginning with $\frac{1}{100}$ to $\frac{1}{50}$ of a grain, the dose is gradually increased to $\frac{1}{4}$ or $\frac{1}{3}$ gr. which should rarely be exceeded. The injections are repeated every other day. Only pure preparations should be used such as are made synthetically by certain German chemical houses. The technique is very simple, the main point being to secure perfect asepsis. After the vein is made prominent, the needle is plunged slantingly into it. The duration of treatment varies considerably, depending upon the severity of the infection. Cinnamic acid is the efficient constituent of the balsam of Peru. The compound used for injection is the sodium salt of this acid, called hetol. It possesses all the efficacy of the original balsam and is free from its defects. The injections are entirely harmless. There are no bad effects on the kidneys. There is no diminution of the red corpuscles. The first effect is the increase in number of white corpuscles for from three to eight hours, after which they gradually decrease to normal. In a few weeks new blood-vessels spring up and granulations extend into the tuberculous area, absorbing and replacing the necrotic material. Many of the patients become drowsy after the injections. The writer has been favorably impressed by the use of this drug, believing that it will markedly quicken healing-processes in some though not in all of the cases.

Where the Danger Lies in Tuberculosis.—Adelaide Dutcher gives the following summary of tabulation:

Total number of patients	190
Number of houses occupied	234
Whites	130
Blacks	40
Russians	20

	Russians, Per Cent.	Blacks, Per Cent.	Whites, Per Cent.
Bad sanitary location	69	40	30
Insufficient light and ventilation	83	71	46
Overcrowding	76	50	46
Personal and household cleanliness	75	66	43

The writer has made her observations in Baltimore. The Russians are separated from the rest of the whites on account of their extreme unsanitary condition. The occupation of many of these patients confines them within doors, and the writer emphasizes their disgusting habits in regard to the disposal of sputum. Her statistics, although limited, show the rapidity with which Baltimore houses are becoming centres of infection. In the short time of these observations these one hundred and ninety patients occupied two hundred and thirty-four houses. There was never any attempt at disinfection. In fifty-eight per cent. of the cases the family history was absolutely negative. When the tuberculous patient is taught to destroy his sputum, to rid his room of carpets and other germ catchers, and to throw open his windows to admit the sunshine and fresh air, a visible decrease in this disease may be looked for in our dispensaries.

A Clinical Lecture on Varix.—The following clinical classification of varix is made by William Thorburn: A. Developmental varix, in which a large trunk stands out from a limb whose tissues are otherwise healthy. This condition is often unilateral. The patient is often young. It is more common in males. There is often a history of hereditary tendency to varicose veins or to hemorrhoids. These cases have probably a congenital origin. B. Obstructive varix, in which the varix is far less sharply limited. It is bilateral after the earliest appearance; rare in the young, more common in the female. Obstruction of the venous return is the prominent cause. C. Hyperæmic or inflammatory varix, in which there is no varix of the larger trunks but only patches in which the venules are enlarged. These small varices are probably a direct result of inflammation, and of prolonged hyperæmia connected therewith, due to long-continued increase in the arterial blood supply. In the lower limb this condition is not common. As to treatment the excision of varicose veins, however performed, is capable of relieving the patient of dilated areas and of developmentally imperfect vessels; it is not capable of relieving obstruction except by the indirect method of substituting healthy for valveless channels. When the defect is limited in extent the best results will be obtained. When it is more widely distributed operation is far less successful. In the obstructive type, the success will largely depend upon the relative etiological importance in each case of developmental error or of obstruction.

A Case of Acute (Traumatic) Tetanus Successfully Treated with Antitetanus Serum.—Sydney H. Long reports the case of a boy aged thirteen, whose foot had been punctured by nails in his boot. Five days later he was admitted into the hospital with symptoms of tetanus. The maximum daily number of spasms occurred on the fourth day after the serum treatment was commenced, after which they gradually declined. This was to be expected, as the toxin had had seven clear days to produce its effects before the serum treatment was begun; and the operation required for the hypodermic injections in part explains the frequency of the spasms. In less than two months he was feeling perfectly well. The study of this case confirms the belief that cases of acute tetanus can be successfully treated with the antitetanic serum if this is given in sufficiently large doses and frequently repeated. It is probably not necessary to resort to the intracerebral method of administering the serum, provided that this be given in sufficient amount. In serum-therapeutics the chance of ill-effects from overdosage is remote. At first the injections were given subcutaneously, but later per rectum. The latter were given through a flexible rubber tube of small calibre under hydrostatic pressure, about an ounce of pancreatized milk being used to drive the serum into the bowel; a plain warm-water injection of a pint was given daily to wash out the rectum while the enemata were being continued.

Erythematous Rash due to Boric Acid.—Henry Handford reports this case. The patient, a man of forty-seven, had suffered from dyspeptic symptoms for three years. Vomiting had been noted for fourteen months, and strength and flesh were diminishing. A non-malignant stricture of the pylorus was diagnosed. The stomach had been washed out for three and one-half months, but it was decided to continue this treatment for a short time longer, and boric-acid lotion 1:60 was selected. About two and one-half pints of the warm solution were used and allowed to remain two or three minutes, and returned by the siphon action of the tube. This was repeated two or three times till the fluid was nearly clear. Within less than a week an erythematous rash appeared on the face and back. Plain water was substituted for the boric solution and the rash disappeared in two days. Again boric solution of a strength of 1:200 was used for three days and the erythema again appeared. The solution was stopped and the rash disappeared. Later the trouble was found to be a much thickened pylorus. Pyloroplasty was performed and the patient made a good recovery.

A Case of Aortic Aneurism Treated by Hypodermic Injections of Gelatin.—This patient was a man of fifty. Arthur Cutfield began the treatment by injecting a two-per-cent. solution of gelatin into the subcutaneous tissues of the abdominal wall on July 22d, using at first three fluid-ounces and after the fourth injection four ounces. The injections were given every second day for about three weeks, and then every third or fourth day, twenty injections having been given altogether. Improvement began in about a fortnight, and from that time the pain steadily diminished and the pulsation became less marked, till at the close of the treatment pain was practically absent and pulsation felt only on deep pressure. He was then quite comfortable except for an occasional spasm once or twice in the twenty-four hours. The improvement was very marked. He was not confined to bed during the treatment, though he moved about very little and with great care. He took five-grain doses of potassium iodide three times a day, and his food and drink were somewhat restricted in quantity.

Successful Removal of an Enlarged and Displaced Spleen.—D'Arcy Power reports this case. The patient, a woman of forty-three, mother of two children three years before operation, struck her left side just over the lower ribs. Two years later she noticed her abdomen increasing in size. She had suffered much pain and discomfort. At operation the abdomen was opened and the spleen discovered to be attached by a long pedicle. The organ was removed. The operation lasted an hour and a half from the beginning of the anæsthetic. On the forty-second day after operation the patient went home and has physiologically sustained no inconvenience from the loss of her spleen. Just after removal, the organ weighed two and one-half pounds. The enlargement was due to hypertrophy, the weight being seventeen or eighteen ounces after it had been kept in spirit for six months. Splenectomy seems to be a successful operation in cases of enlarged and displaced spleens when the enlargement is not leucocythæmic.

The Management of the Soft Parts in the Mastoid Operation.—After reviewing Schwartze's and Ballance's operations, James Kerr Love describes the single channel operation. The bone is dealt with as in the ordinary radical mastoid operation. The posterior superior wall of the cartilaginous canal is slit through its entire length. The mastoid skin wound is closely stitched and a careful packing via the external auditory canal causes the slit posterior cartilaginous wall to apply itself to the posterior wall of the widened bony canal. The canal is much widened, through which it is easy to conduct future treatment, which consists almost entirely of packing with special absorbent gauzes. All dressings are removed from the side of the head within a fortnight and the patient may then resume work. Every part of the healing surface can be seen through the speculum. Complete healing takes place within three months, and two dressings per week are generally sufficient.

A Case of Severe Subcranial Hemorrhage; Operation; Recovery.—F. G. Proudfoot and Gabriel W. Farmer report the case of a woman aged fifty-six, who was found lying unconscious. After being put to bed she regained consciousness for a short period, after which she again lapsed into unconsciousness. Operation was advised as the case was diagnosed as being one of subcranial hemorrhage. A trephine was applied and on the removal of the crown of bone a large clot bulged into the wound, and almost instantaneously the stertorous character of the breathing ceased. The clot was scooped away and a large depression in the convexity of the brain presented itself. Hemorrhage was free. The depression was packed with sterilized gauze and a dressing applied. Within a week the sutures were removed. The wound healed completely, and the patient made a perfect recovery.

Note on a Case of Protracted Stupor.—This case is reported by David Drummond. The patient was a man aged twenty-six, with a neurotic family history. When admitted to the hospital, he lay motionless and took no notice of his surroundings. His eyes were open, his limbs cold and flaccid. Reflexes were just perceptible, but the corneal reflex was active. Liquid nourishment was given. The treatment consisted in attending to the skin, and massage with passive movements. At the end of seven months he began to improve, and as he became able to speak it was discovered that his consciousness and memory had not been entirely in abeyance and in this respect the case differed from anergic stupor. It differed from melancholic stupor in that the muscles were flaccid and absolutely unresistive.

Notes of Two Cases of Excision of the Gasserian Ganglion for Epileptiform Neuralgia.—J. Crawford Renton believes that this most severe complaint can now with safety be relieved. In these two cases he removed the ganglion, adopting the method of Hartley and Krause, which he calls the high road. By this method, a flap of skin, fascia, and muscle is turned down, with its base either below or in front of the ear, and a large portion of bone removed by the trephine or burr. The dura was punctured and separated to the foramen spinosum. After exposing the foramina rotundum and ovale the superior and inferior divisions of the fifth were drawn out and divided. The ganglion was then raised up and pulled away. This method is laborious and requires great patience, but seems to meet with excellent success.

Diphtheritic Paralysis.—E. F. Trevelyan presents an analysis of six cases which furnish a starting-point for some remarks on the occurrence of albuminuria and ataxia in connection with diphtheritic paralysis. He concludes that diphtheritic albuminuria has no other relation to diphtheritic paralysis than that both complications are more prone to occur where the diphtheritic intoxication is most intense. The question is not considered here as to whether kidneys damaged by a toxic nephritis are not more likely to lead to the retention within the body of the paralysis-producing poisons than would happen with healthy kidneys. Ataxia is nearly always combined with more or less paresis. Some authors state that the ataxia appears first and then later the weakness. Of course, the weakness would tend to mask the ataxia. It is quite true that it is very unusual to find in diphtheritic paralysis the degree of disorderly movements with the flinging, stamping gait so commonly seen in tabes, but this is no reason why slighter degrees of inco-ordination should not be admitted. Nothing new is stated as to treatment.

The Diagnosis of Plague.—W. C. Hossack makes the following types of disease: the bubonic, pneumonic, septic, intestinal, cerebral, and carbuncular. Under each heading are described the features peculiar to the type. Diseases liable to be confounded with plague are puerperal fever, septicæmia, pyæmia, smallpox, influenza, cerebro-spinal meningitis, diphtheria and angina, erysipelas, measles, gonorrhœa, syphilis, mumps, malaria, cerebral embolism, and scrofulous glands. Of course in some of these maladies there is rarely any difficulty in making a differential diagnosis, but in the course of the writer's personal experience cases have occurred under all these headings in which the diagnosis was at first hard to make.

Fourteen and a Half Hours' Artificial Respiration in a Child One Week Old; Recovery.—The case is reported by G. E. Keith. Chloroform was given for circumcision. The child did not take it well and lost more blood than is usual. He afterward slept for some hours and was apparently doing well. Some hours later cyanosis was observed and the child appeared lifeless. Artificial respiration was begun and in a few minutes all seemed well. Again cyanotic attacks and stoppage of breathing came on, to be again relieved by artificial respiration. This series of events was repeated several times, but finally normal breathing was permanently re-established.

French Journals.

Intoxications and Infections in Mental Troubles and in Neuropathies.—G. D'Abundo concludes that infections and intoxications represent in the pathogeny of general nervous troubles the most frequent and active elements, and this in all conditions of life both intra- and extra-uterine. Toxic-infectious heredity (syphilis, alcoholism) gives a tendency in the descendants to the evolution of neuropathies. Infections and intoxications in the ancestors or in the mother during gestation cause in the fœtus very frequently a striking retardation of development in the nervous system. The action of infectious and toxic agents may produce nervous troubles, peripheral or central, and may lead to neuro psychoses either acute or chronic. Mental confusion represents simply the most frequent clinical type of the toxic-infectious action. Acute delirium may be considered a clinical symptom, caused by various infectious and toxic agents. Researches into the etiology of progressive paralysis only fortify the conception of its infectious and toxic origin. Clinical manifestations of infections and intoxications of the nervous system are the result of more or less pronounced nutritive disturbances. As to the treatment on this basis, it will consist in the elimination of toxic products, and will seek to neutralize or diminish the effects of secondary intoxications.—*La Presse Médicale*, November 3, 1900.

Latent Appendicitis.—Grandmaison reports this interesting case. The patient was a man fifty-one years old. He was a chronic alcoholic, and for fifteen days before entering the hospital his skin had been growing more and more yellow. He suffered a little from vague abdominal pains and from severe diarrhœa and slight headache. The diagnosis was that of infectious icterus occurring in an alcoholic and accompanied by atrophic cirrhosis of the liver. The patient was put on a milk diet. The three signs that would be at once looked for in appendicitis were absent: excessive abdominal pain, intestinal obstruction, and symptoms of peritonitis. At the autopsy—the patient died on the fourth day after entering the hospital—the appendix was found to be distended and perforated, and a sero-purulent collection was found behind the cæcum, as well as a generalized peritonitis.—*La Médecine Moderne*, November 7, 1900.

Dysentery in Brittany; Colon Bacillus in the Waters of Landerneau.—E. Lenoble speaks of his work and that of his associates in regard to the analysis of the waters of Landerneau in the midst of the affected region. They used various methods. The nutritive gelatin plates of Ellsner showed colonies of the colon bacillus, the method of Péré gave analogous results. To sum up the results of the whole work, there was found an undeniable variety of colon bacillus, which resembled to a certain extent Eberth's bacillus but was clearly distinguished by certain characteristics, *e.g.*, the lactose test which differed from the reaction with Eberth's bacillus and the absence of Widal's test.—*La Presse Médicale*, October 27, 1900.

The Relations between Alopecia and Dental Lesions.—L. Jacquet calls attention to the resemblances between the skin and the teeth, from the points of view embryological, histological, and evolutionary. He believes that deficiency of various salts has much to do with these conditions. There is probably a vitiation of the general trophic sytem. Dental troubles and baldness are becoming very common and can but call attention to the theory of the evolution of a human type which will be toothless and hairless.—*La Presse Médicale*, November 10, 1900.

Berliner klinische Wochenschrift, Nov. 5 and 12, 1900.

Nephrectomy for Calculous Pyelitis.—L. Thumim reports the case of a woman of thirty-one years, whose urine contained pus and who suffered from the symptoms of renal colic. Cystoscopic examination showed cystitis, but catheterization of the ureters failed to reveal any changes in either kidney nor was there sensitiveness in their neighborhood. Later attacks of pain led to a repetition of the catheterization and evidences of a pyelitis of the right kidney were manifest. By means of the Casper-Richter phloridzin test it was also determined that the parenchyma of the right kidney was involved and its removal was advised. This was done and the patient made a good recovery. Several calcareous masses were found in the extirpated organ.

Purpura Rheumatica and Angina.—A. Bruck refers to the abundant literature of recent years on the general subject of the relation between sore throat and rheumatism, and then relates the histories of four cases occurring in his own

practice in which manifestations of ordinary tonsillitis were followed by a typical petechial rash of a purpuric type. He believes that in such cases the poison gains entrance through the tonsillar structures and then affects the system at large. It is not necessary that the throat symptoms should be of a severe type. Often they are very mild and yet the constitutional rheumatic symptoms very severe.

Post-Mortem Appearances in a Case of Acromegaly.—E. Mendel gives the findings in a case which had been under observation for some time. The article is illustrated by two drawings and should be consulted in the original by those interested in these cases. At the base of the brain in the region of the chiasma a walnut-sized sarcoma was found, made up of large round cells. The pineal gland was normal throughout. The thyroid gland was considerably enlarged. The spleen was large and soft. The thymus gland was present.

The Treatment of Catarrhal Adhesive Processes in the Middle Ear by Means of Intra-Tubular Pilocarpine Injections.—Fischenich advises the use of muriate of pilocarpine in two-per-cent. watery solution. The dosage should commence with six to eight drops for each ear and gradually increase to twelve or even sixteen. These are injected through a catheter in the usual manner. From thirty to fifty injections may be necessary in some cases. Sometimes a little dizziness and even pain is felt at first, but only for a short time.

Münchener medicinische Wochenschrift, Nov. 13, 1900.

The Subjective Symptoms of Neurasthenia.—L. Hoeflmayer considers that the more or less generic term "neurasthenia" should be replaced by more specific appellations indicating the system diseased, *e.g.*, there are well recognized cerebral, spinal, visceral, intestinal, and cardiac forms of the malady. If all the subjective disturbances of neurasthenics be collected and studied it will be found that they may be grouped under two headings, viz., (1) disturbances of intestinal activity and (2) vagus-sympathetic neuroses. The intimate relationship between these two sets of causes is clearly shown by the great relief afforded in nearly every case of such disease by a thorough and systematic cleansing of the intestinal tract. One of the commonest and at the same time most alarming symptom complexes to which the neurasthenic is subject is a form of angina-like attack, attended by great cardiac distress, dyspnœa, rapid feeble pulse, cold clammy extremities, and which on inquiry is found to have been preceded by several days' constipation. It is impossible to be certain whether the irritation of the intestinal connections of the vagus is the result of the mechanical or the chemical stimuli resulting from the presence of the inspissated and decomposing fecal masses, but that they are the *causa morbi* is shown by the almost instantaneous relief to all the symptoms after satisfactory clearing of the intestine has been secured by copious high injections.

The Typical Form of Laryngeal Neuralgia.—Georg Avellis has found that otherwise perfectly healthy individuals, who are above the suspicion of hysteria, may be found to suffer from a painful affection of the larynx, which is increased by motion of the part, and may become so severe as to cause the patient to refrain from eating or speaking through fear of the pain attendant on these acts. The one sign which differentiates this from all other similar affections and at once stamps it as neuralgic in nature is the existence of true points of tenderness where the nerve involved pierces a layer of fascia; namely, pressure over the spot where the superior laryngeal nerve pierces the thyro-hyoid membrane and also where it lies superficially in the pyriform sinus elicits the characteristic pain. Local treatment by means of sprays, etc., is unavailing, but the internal use of antineuralgics and external application of dry heat are speedily successful. The differential diagnosis lies between this affection and rheumatism of the cervical muscles, bursitis lateralis, and hysteria.

A Case of Formalin Poisoning.—Ludwig Zorn's patient accidentally took about four drachms of the commercial forty-per-cent. solution of formalin. Immediately after swallowing the liquid, realizing his error, he took some milk which was instantly vomited. When he came under observation he was suffering from dyspnœa, vertigo, great anxiety, burning in the mouth and stomach, and nausea. The pulse was rapid and small, and after twenty-four hours of absolute anuria a small quantity of albuminous urine was passed. For several days there was diarrhœa of moderate intensity and the patient was discharged cured a day or two later. It is interesting to note that in this case the gastro-intestinal and renal symptoms occupied the foreground, while in that recently reported by Klüber in the same journal it seems to have been the sensorium that was most affected.

A Case of Tetanus following Poisoning.—F. Dammer describes a case of what appears to have been true tetanus following the use of an anthelmintic containing extract of male fern and calomel. The patient was a woman of thirty-five, who years previously had taken a similar dose with no unpleasant results. At the present time the expulsion of the parasite took place one and one-half hours after the medication, but was promptly followed by temporary loss of consciousness, and convulsive seizures in every respect resembling those of true tetanus. These were repeated at short intervals, but under treatment by hydrotherapy recurred less often, and finally the patient was discharged cured three weeks later.

OUR LONDON LETTER.

(From our Special Correspondent.)

WEATHER AND HEALTH—CLINICAL SOCIETY—SEQUEL TO HYDATID CASE; ABDOMINAL SECTION AND ASCITES—SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN—SIR W. THOMSON—MR. MAKINS—PROFESSOR YOUNG—DEATHS OF DRS. EMBLETON, QUINLAN, TAUNTON, PALMER, ANDERSON.

London, November 16, 1900.

Up to the present we have had no cold weather to speak of. In London, indeed, it seems a particularly mild November, and the impression is confirmed by the meteorological statistics, which show a temperature of 13° above the average for this month. This is said to be due to a series of depressions from the Atlantic, bringing mild southerly breezes and warm rains all over the country, though the total rainfall is not heavy. The indications seem to be that warm, moist, showery weather will last longer.

The effect on the public health will not be evidenced for some time yet, though many people are assuming that it will be bad, and assuring us that frosty air is more wholesome.

At the Clinical Society on the 9th Dr. Norman Dalton read the sequel to a case of hydatids of the liver, showing also the results of abdominal section on ascites. The patient was a girl, who at eleven years of age passed hydatids per rectum and expectorated bile from the right lung. She recovered, but at sixteen ascites set in. After some tappings, at fortnightly intervals, abdominal section was performed, but nothing found which could be removed. There were then no adhesions except at the top of the liver, round the fistula into the lung. Two subsequent tappings were called for in the next fortnight. The girl then got well and continued so for five years. Examination then showed a small quantity of fluid in the hypogastrium, but the rest of the peritoneal cavity seemed to be obliterated by adhesions. In May, 1899, the patient died of septic peritonitis at the age of twenty-three. At the post-mortem the old cyst was found communicating below with a dilated bile duct, and above, through the diaphragm, with a dilated bronchial tube. There was a collection of fluid in the hypogastrium, and adhesions obliterated the rest of the cavity, just as had been surmised. Thus the ascites had been practically cured, and Dr. Dalton thought this was due not only to the occlusion of the cavity, but to the portal congestion being relieved by the opening of communications between the portal capillaries and those which joined veins in the abdominal wall, diaphragm, etc. The case seems to encourage abdominal section for ascites, as for ten years the patient was pretty well, the condition being that of cirrhosis.

Sir R. D. Powell said hepatic cirrhosis associated with ascites was favorable when adhesions formed, and their presence might be inferred from uneven distribution of the fluid. He mentioned such a case, and agreed that the

adhesions set up another circulation, and so relieved the portal congestion.

Mr. Marsh pointed out that Mr. Morison, of Newcastle, had operated in these cases for the express purpose of obtaining this collateral circulation by setting up adhesions.

Dr. Rolleston referred to the paper which he and Mr. Turner brought before the Medical Society a year ago on this subject. Their statistics, as I mentioned at that time, showed that out of fifteen cases operated on, five were cured. They agreed that the collateral circulation had some influence, but it was not a sufficient explanation alone, as other symptoms were also relieved. Probably more blood being brought to the surface of the liver, its nutrition was increased and its cells became hypertrophied.

Mr. Morison thought the adhesions acted by diminishing the size of the cavity, which increased the aspirating-power of the thorax. It was an old and successful plan to compress the abdomen after paracentesis by encircling it with strapping to be worn for a long time.

Dr. Toogood supported the view that adhesions acted by increasing the aspirating-power. He related a case in which ascites had disappeared after laparotomy. Dr. Norman Dalton in his reply said a serious consideration was the likelihood of hernia, and he believed that his patient eventually died of that.

The Society for the Study of Disease in Children has gone vigorously to work, and a number of interesting cases have been exhibited at its meeting. Among these may be named that of an infant aged eight months, weighing twenty-nine and one-half pounds. The child had been fed exclusively by the breast. The maternal milk had a great excess of lactose. The child seemed otherwise healthy. A case of myxœdema with ectropion in a girl aged twelve years, brought by Mr. Sidney Stephenson. In connection with this case Dr. Percy Lewis showed photographs of other cases of myxœdema in young subjects. A lad aged five years, with Mongolian imbecility, on which some members offered remarks. There was also shown a specimen of a heart weighing nineteen and one-half ounces. It was dilated and hypertrophied. The child died a year after an attack of acute rheumatism.

The court of appeal has reversed the decision in Dowling *v.* Dods. The action was one for libel, and Dr. Dods was cast in damages for a letter in which he stated that Miss Dowling was not sane. The letter was sent on account of plaintiff being a candidate for a dispensary appointment. The learned judge said it was perfectly plain the lady's mind was unhinged and there was not a scintilla of evidence of malice. It seems Dr. Dods merely gave a warning of the danger of any one subject to hallucinations acting as a dispenser.

Sir William Thomson has been appointed surgeon to the Queen in Ireland. This is no more than was to be expected, since to his great position as a surgical leader in Dublin he added that of chief of the Irish Hospital at the seat of war.

Mr. G. H. Makins, of St. Thomas' Hospital, who went to South Africa as one of the consulting surgeons, is engaged on a book giving an account of his experience there.

Professor Young is to succeed the late Dr. Leech as representative of Victoria University in the General Medical Council.

Dr. Dennis Embleton, consulting physician to the Royal Infirmary of Newcastle-on-Tyne, died on the 12th inst. at the advanced age of ninety. He was for a long time a member of the General Medical Council. In earlier days he taught anatomy, physiology, and medicine, and there are men still living who delight to recall the assistance he gave them. But his interest in literature and natural history was intense, and these subjects occupied much of his time and attention. This venerable member of the profession had declined in health for the last few months.

Dr. F. B. Quinlan, of Dublin, died on the 9th inst. He was for a long time physician to St. Vincent's Hospital and professor of therapeutics in the Catholic University. He graduated in 1857 at Dublin University, and in due time became a member of the senate. He contributed many papers to the societies and journals, and was esteemed as a scholar outside professional subjects. He was the son of a journalist and had much interest in literary subjects, though not to the detriment of his medical sentiments. He retired some ten or twelve years ago. His death was not unexpected, as he had been ill for some time and in bed for several weeks. He had reached his sixty-fifth year.

Another venerable member of the profession, Thomas Taunton, died on the 5th inst. in his eighty-ninth year. He was a skilful surgeon and very successful accoucheur. It was stated that he had never lost a midwifery case.

Yet another octogenarian: Father R. F. Palmer took his M.R.C.S. diploma in 1846 and practised until 1853, when he entered the Roman Catholic Church, became a priest, and devoted himself to historical, ecclesiastical, and antiquarian studies. He was given the degree of master of theology.

The death is also announced of Mr. R. B. Anderson, F.R.C.S. Eng., formerly of Tobago, and whose name you will no doubt remember in connection with the subject of medical reform.

UNIVERSAL ANKYLOSIS.

To the Editor of the Medical Record.

Sir: Dr. H. A. Elliott's account of a case of universal ankylosis, in the Medical Record for November 17th, recalls a similar case which I saw in Buffalo in 1887 or 1888. This case was on exhibition as the "ossified man." He was also exhibited in Boston and other eastern cities a year or two later. I made no notes of the case, but my recollection is about as follows:

He was a native of Western New York, about fifty years of age, and had been in his then present condition for a number of years. Every joint in his body was absolutely solid, the only motion being at the shoulders, by the sliding of the scapulæ in the muscles at the back of the chest. He lay with legs fully extended and one arm semi-flexed, and the attendant, by placing a hand under the occiput, would raise him from the couch like a log of wood, resting only on heels and head. Some of the bones of the fingers had disappeared from absorption, and as his nails had been allowed to grow for years they hung in spiral ribbons three or four inches long, giving the hands a most uncanny appearance. Several teeth had been removed to allow nourishment to be taken, as the jaw was firmly set.

His mental faculties were perfectly clear, as shown by his conversation with those about him, but he was totally blind. Taken all in all, his case seemed about the most pitiable I have ever witnessed.

F. B. Storer, M.D.

Holley, N. Y., November 21, 1900.

LETTER FROM NEW ZEALAND.

(From our Special Correspondent.)

Auckland, October 27, 1900.

The session of our legislature has just closed, to the great relief of every one. We never know what mischief may be done, and when the houses are prorogued we feel like the parents of disobedient and disorderly children when the latter are in bed and asleep for the night. During the session a new public-health act has been passed under the influence of the plague scare, giving despotic powers to the central board of health, and entirely superseding the local boards, which are now reduced to the function of carrying out the orders of the central authority.

Among other changes effected by the new sanitary act, vaccination has been made so far voluntary that on a parent satisfying the magistrate that he has a "conscientious" objection to vaccination the magistrate must give him a certificate exempting the child from vaccination. This is not quite so complete a release as the English law affords, but it will have to be brought into line with the latter before long. The reason why there has been hardly any public outcry against vaccination here is because the compulsory clauses have never, or hardly ever, been enforced. Smallpox has been introduced into the colony several times to my own knowledge, but with only an imperfect system of quarantine it has been kept from spreading. Of late years calf lymph has been used. But a large majority of the children are unvaccinated.

We hear no more of the plague. Some weeks ago I saw a case which was very suspicious, and was isolated for a few days, but it was declared not to be the plague. The patient, a man of about sixty, had been ill four or five days, with not very high fever, some delirium, and a very curious mass of buboes, extending to the size of one's hand equally above and below Poupart's ligament on the right side. There were no local lesions to account for these buboes. The surgeon in attendance and the local medical officer of health agreed with me in thinking the case so suspicious that it ought to be isolated. It was a very mild case, the temperature being only about 100° F. The medical officer of the Plague Hospital (a very pretty young lady with a fluffy fringe, whose experience as a qualified practitioner was of about four months' duration, and acquired only in the colony) scouted the idea of its being plague, and dismissed the case in a week. No other case has occurred. The fact is, that beyond influenza, and every few years scarlatina, we cannot get up a good lively epidemic. Even diphtheria seems to be dying out. Fortunately for some of the profession there are plenty of chronic diseases, and by performing a laparotomy on everybody who complains of belly-ache, they manage to exist. The colony is too healthy; if the women would throw away their corsets and dress rationally, four-fifths of the doctors would starve.

Society Reports.

THE PRACTITIONERS' SOCIETY.

One Hundred and Fifty-eighth Regular Meeting, Held on Friday, November 2, 1900.

A. Alexander Smith, M.D., in the Chair.

A Case of Large Renal Calculus Detected by Radiograph; Pyuria without Hemorrhage; Operation; Recovery.—Dr. Robert Abbe presented a man thirty-two years old, who had had an attack of right renal colic nine years ago. His symptoms at that time were relieved by a fly blister, and there was no recurrence until two years ago, when he suffered from intermittent pain in the region of the right kidney, which lasted for three weeks. There was no blood in the urine. Again, during the past six months he had had a recurrence at times, and more recently the pain had been quite constant. His urine had appeared muddy for a year. He had been losing flesh, but he had had no fever so far as he knew. Examination showed a large movable tumor in the right hypochondrium, which felt like a renal sarcoma. The pyuria suggested a tuberculous kidney, but repeated examinations of the urinary deposit failed to reveal tubercle bacilli. A radiograph showed a large branching calculus, with two separate pieces. On June 15, 1900, Dr. Abbe performed lumbar nephrotomy and removed the large calculus, but a careful search with the finger, metal instruments, and needles failed to detect the two outlying pieces which were shown in the radiograph. A bistoury was freely used inside the kidney to cut through all partitions of the numerous pockets. Three weeks later, when the kidney had contracted, digital and instrumental search—without ether—revealed the remaining calculi protruding from separate pockets, and by cutting around them they were easily dug out. Since the operation the patient had gained twenty pounds in weight. He still had a pus-discharging sinus which would doubtless close in the near future. In connection with this case, Dr. Abbe exhibited the radiograph which had revealed the presence of the renal calculus.

Dr. Abbe also showed a radiograph of a phosphatic stone in the kidney of a woman who had suffered from pyuria for two years. During this period she suffered from fever and had become much emaciated. A small tumor could be made out in the region of the kidney. There was no history of hæmaturia, and the symptoms were suggestive of tuberculous kidney. A radiograph showed a faint shadow, indicating the presence of a renal calculus. An incision revealed a pyonephrosis, and a soft phosphatic stone an inch and a half long, but weighing not more than thirty grains. The patient made an uneventful recovery. Dr. Abbe said that as a rule a phosphatic calculus, on account of its lightness, was very difficult to make out with the *x*-rays. On the other hand, the oxalate of lime or mixed calculi usually showed very well. He exhibited two other calculi detected and removed after radiography, the smaller one weighing only eight grains.

Dr. E. G. Janeway asked Dr. Abbe whether, in any of his cases in which an operation was done for the removal of renal calculi upon the evidence furnished by the radiographic picture, no stone was found. Dr. Janeway said he had heard of such cases.

Dr. Abbe replied that no such instance had come under his observation. The greatest care should be exercised in taking these radiographs; unless the plate was well protected by gutta percha, it might become dampened by the moisture of the skin and give rise to a false shadow simulating a stone in the kidney.

Dr. Francis P. Kinnicutt said that during the past summer he had seen a case in which the radiograph showed multiple stones in both kidneys. Surgical interference had seemed contraindicated on account of the number of the calculi.

Dr. Abbe said the conditions mentioned by Dr. Kinnicutt did not appeal to him as legitimate grounds for refusing to operate. Usually after the removal of stone the urine was voided into the bladder and the sinus closed. When both kidneys were involved, one kidney at a time could be taken.

Dr. Janeway said that in such a case suppression from the other kidney was liable to occur.

Dr. George L. Peabody said that in certain cases the kidney might be so seriously disorganized by stone that restoration of function could hardly be looked for.

Dr. Abbe said he did not refer to cases of suppurating kidney with stone. He understood that the case mentioned by Dr. Kinnicutt was one of multiple stone with hæmaturia.

A Case of Multiple Gall Stones in the Gall Bladder, Simulating Cancer.—Dr. Abbe showed a collection of three hundred and forty-three gall stones, varying in size from a bean to a small hen's egg. The history of the case was as follows: The patient was a woman sixty years old, who had never had gallstone colic, but who for three months past had suffered from abdominal pain and loss of weight, about two and one-half pounds weekly. She had no fever; her urine contained bile, and the stools were clay-colored. Jaundice came on slowly during the last ten days. There was a tumor on the right side of the abdomen which had slowly grown to the size of a cocoanut, and on account of its mobility her physicians regarded it as a movable kidney. She had the exhaustion of profound cholæmia, and just before she came under Dr. Abbe's observation this nearly proved fatal. Examination by Dr. Abbe showed a cocoanut-shaped tumor which was so movable in the abdomen that it bobbed about and could be moved down to the groin and nearly across the median line. When at rest it was below the right ribs. The mass was brought over to the median line, and under cocaine anæsthesia, aided by a few whiffs of chloroform, it was evacuated through a median incision, a pint of white glairy fluid and three hundred and forty-three gall stones being removed. The bile immediately began to flow freely through a tube in the distended gall bladder, and the patient made a perfect and very rapid recovery.

Dr. Peabody said that gall stones were not infrequently found post mortem in people who had never given a history of biliary colic.

Dr. Janeway said that gall stones in the common duct might produce obstructive jaundice without any biliary colic. Of five cases of this kind which had come under his observation, three were operated on and two of the latter were fatal. One was of a physician who had never complained of biliary colic; he died after an operation for the relief of jaundice which was due to the presence of a large stone in the common duct. A second case was that of a young married woman who had suffered from obstructive jaundice for a number of years. There was no history of biliary colic. It was thought advisable not to operate in this case, on account of the danger of hemorrhage incident to the long duration of the jaundice. This patient also suffered from profuse menorrhœa, and died about a year after she first came under Dr. Janeway's observation. The post-mortem showed a stone in the common duct, and the duct itself was very adherent.

Dr. Beverley Robinson said he had seen cases in which an operation failed to reveal the presence of gall stones, in spite of the fact that the history and symptoms of the patient pointed that way. He recalled

one such case which had been operated on for him by Dr. Bull. The patient finally recovered under stomach lavage. In a case of supposed impacted gall stone which was operated on at St. Luke's Hospital the patient died of subsequent hemorrhage.

Dr. Janeway, in reply to a question as to how long after the onset of the jaundice he would advise against operation, said that this would depend upon the cause of the obstruction. In obstruction due to cancer of the common duct an operation might produce fatal hemorrhage within four or five months after the onset of the jaundice. The speaker said he had seen six fatal cases of this kind, each one operated on by a different surgeon. In obstruction due to stone it was safe to operate after a much longer period—perhaps within two years.

Dr. Kinnicutt said that he usually advised against operation in these cases in the presence of cholæmia on account of the danger of fatal hemorrhage. He had seen several cases in the past few years in which, with a moderate degree of cholæmia, a fatal issue from secondary hemorrhage had followed operation.

Dr. Robinson referred to a case of obstructive jaundice supposed to be due to gall stones, in which death occurred in a convulsive seizure. There was no autopsy.

Dr. Joseph D. Bryant said he had had one case of fatal secondary hemorrhage after an operation for gall stones.

Dr. Abbe, in closing the discussion, said that in his case the jaundice had lasted only ten days. The symptoms closely simulated those of cancer, and the patient nearly succumbed to exhaustion from the profound cholæmia. There was nothing found but this collection of stones, and the patient made a rapid recovery.

A Case of Peritonitis from Perforation of the Stomach Wall by a Toothpick.—Dr. Abbe reported this case. The patient was a man aged fifty years who had suffered for two months from symptoms closely resembling those of gastric ulcer, to wit, pain and tenderness in the epigastrium, more severe after eating, always coming on between meals and passing away entirely before the following meal. Two weeks before operation the pain became much worse, and was accompanied by nausea and vomiting.

On examination the abdomen was found to be distended, the epigastrium hard and full, and there was muscular rigidity of the upper recti and on the right side of the lower half. The diagnosis of appendicitis had been made before Dr. Abbe saw the patient, because of tenderness in the lower abdomen, which was more marked on the right side. The epigastric condition, however, clearly indicated perforating ulcer. The patient had a temperature of 104° F., and his general condition was such that an immediate operation was indicated. An incision was made above the navel and a matted mass of intestine uncovered, from which protruded the blackened end of an ordinary wooden toothpick; the other end of the toothpick was still embedded in the ulcer of the stomach wall. No gas was noticed in the foul abscess, which was still confined by the matted omentum, but spreading downward to the navel. The wound was packed and left open. The temperature was normal on the sixth day, and prompt recovery followed.

In connection with this case, Dr. Abbe exhibited the toothpick. The patient had no recollection of ever having swallowed it, and had never been intoxicated, so as to have the swallowing occur without his knowledge.

Pernicious Anæmia and its Relation to Inheritance.—This paper was read by Dr. C. L. Dana (see page 841).

Dr. Robinson said that in the November number of the *American Journal of the Medical Sciences* Dr. Billings reported twenty cases of pernicious anæmia, in two cases of which the patients were over sixty years of age, and in two, sixty years old.

Dr. Peabody said that Dr. Dana's paper was most suggestive and deserved careful reflection. While it was not always safe in pathology to reason by analogy, the array of analogies presented by Dr. Dana was very striking. The fact that several cases of pernicious anæmia had occurred in the same family had been noted before, and was strictly in line with the author's suggestion.

Dr. Kinnicutt said that while a family history of pernicious anæmia was occasionally gotten, he doubted whether this fact could be looked upon from the point of view suggested by Dr. Dana. The speaker said that a family had been under his observation in which three of the children had suffered from pernicious anæmia. One of them died; the other two were still living. Of the latter, one had had two relapses. All three of these cases were instances of pernicious anæmia, based upon our present knowledge of blood examinations. None of these patients displayed any other congenital peculiarities or weaknesses than a congenitally large spleen, and this same condition had existed in the father and paternal grandfather.

Dr. Robinson referred to one instance that had come under his observation in which a simple anæmia had apparently developed into pernicious anæmia. This seemed to be the opinion of those who made the blood examinations. The latter, however, would not always decide the question, and the clinical evidence must also be depended upon.

Dr. Kinnicutt said that on Dr. Dana's theory it would be difficult to explain the spontaneous and very rapid and marked improvement which was often seen in cases of pernicious anæmia, with or without treatment. A case of pernicious anæmia which had been regarded as hopeless might begin to improve and apparently result in recovery. Clinical experience pointed to the certainty of a relapse, however, even if the period of freedom lasted two or three years, or even longer. In these cases the blood occasionally recovered its normal condition, so far as our present methods of examination permitted us to judge. Such an improvement was difficult to explain on any supposition. Probably the most plausible was that which attributed the anæmia to the presence of a toxin.

Dr. Dana said that interims of improvement were seen in other degenerative diseases, such as paresis and the various muscular dystrophies.

Dr. Kinnicutt said that while in certain degenerative diseases the symptoms might remain stationary, in pernicious anæmia the constituents of the blood often became both quantitatively and qualitatively normal during the period of improvement.

Dr. Janeway said that while Dr. Dana's theory regarding pernicious anæmia was very suggestive, he did not feel inclined to accept it. Before doing so, it would be necessary to analyze a great many of these cases and enter very fully into the family history. There were no doubt cases of pernicious anæmia in which an hereditary history of the disease could be obtained.

Dr. W. Gilman Thompson said it was interesting to have heredity advanced as a factor in disease, for in recent years it had been relegated more and more to a minor rôle, as in phthisis and rheumatism. Before Dr. Dana's theory was accepted, however, the potency of heredity in these cases should be well established. Dr. Dana's patient evidently belonged to an interesting family and inherited certain weaknesses, but this did not prove that the pernicious anæmia was necessarily due to an inherited blood dyscrasia. The speaker said he had looked over the records of a num-

ber of his cases of pernicious anæmia in which the patients' antecedents and family history were very carefully investigated, and had failed to find a single instance in which heredity could be claimed as a factor. On the other hand, Dr. Thompson said, there were one or two blood diseases that seemed to be distinctly hereditary. The most extraordinary hereditary condition was hæmophilia, which was transmitted by females but rarely shared by them. This condition had been traced back for several generations. Certain cases of chlorosis also seemed to be hereditary. While the possibility of an hereditary dyscrasia in pernicious anæmia could not be denied, evidence was still lacking to prove it. There might be an hereditary weakness of the general constitution, which might lead in one case to a blood disease like this, in another to muscular dystrophies, neuroses, and so on. It should be borne in mind that the accurate diagnosis of all blood disease was of recent date, and comparison of early records was unreliable. The possibility of chlorosis merging into pernicious anæmia was denied by many, but there were cases in which the severe form of chlorosis and the mild form of pernicious anæmia caused blood changes which were very difficult to distinguish from each other. There were cases which were apparently on the border line, just as in leukæmia and pseudo-leukæmia, and the etiology of all these blood diseases was not at all established. In conclusion Dr. Thompson said that while he was much interested in the theory of Dr. Dana, the arguments in its favor did not appeal to him as convincing. Other theories, particularly that of auto-intoxication, appeared more plausible.

Dr. C. N. B. Camac said that Dr. Dana's etiological explanation of pernicious anæmia upon teratological grounds opened up an entirely new line of thought. In reviewing the history of the cases of pernicious anæmia reported in literature, one was struck by the omission of any reference to family history. The most extensive report in connection with the subject was probably that of Hunter in *The Lancet* of last year. In the description of the cases that appeared in this report family history was not given in a single instance. Except only in text-books on medicine in which such history was a matter of systematic arrangement, nowhere did family history appear, and even in these no reference was to be found to miscarriage, etc., which was the striking feature in Dr. Dana's case. It was therefore important, in order to verify this theory of Dr. Dana's, that this portion of the history be more thoroughly inquired into, in the future. It was perhaps natural that Hunter should have omitted this inquiry as to family history, as he attributed the disease to the absorption of toxins resulting from pathogenic micro-organisms taken into the digestive tract, and reported two cases in which sewer gas appeared to be a source of infection. Adami, of Montreal, had reported four cases in which he suggested that a chronic gastro-enteritis was the seat of the trouble. He believed that, as the gastro-intestinal tract gradually became impaired, the resistance to the ordinary micro-organisms, which were harmless in the healthy gut, was overcome, and ultimately the blood suffered and toxic effects were noted. If the theory of irregular longevity of different organs in the same individual was correct, as Dr. Dana suggested in connection with the blood-making apparatus, the digestive apparatus might also be considered to fail earlier in some individuals, and thus this theory and that of Hunter and Adami would be in accord. Continued hæmolysis we knew might in time lead to a faulty hæmogenesis. Evidence of this was given in the blood characteristics of secondary anæmia of long standing giving place to those of primary anæmia, with normoblasts, gigantoblasts, etc. Thus the hæmolysis of the theory of Hunter and Adami would hasten the hæmogenetic failure in the theory suggested by Dr. Dana. Dr. Camac said that if Dr. Dana's idea were correct we might find an interesting field for investigation in the blood of the aged. We might find in the peripheral circulation of old persons some of those bodies, normoblasts, gigantoblasts, etc., associated with failure of the blood-making organs.

Dr. Dana, in closing, said that in spite of the researches made in connection with toxins and gastro-intestinal disturbances, they failed to explain in a satisfactory manner the cause of pernicious anæmia. A disease which came on without apparent cause, which progressed steadily, and proved fatal in the course of a few months, in spite of the fact that all the other organs in the body were in a fairly healthy condition, suggested to him a striking analogy to the degenerative diseases which he met with in the nervous system and in other parts of the body. In such degenerative diseases neuropathologists generally admitted that there was an inherent weakness in certain groups of neurons. In connection with pernicious anæmia it would require long and careful research to establish this view. The speaker said he did not mean to imply that the disease was hereditary in the sense that it was directly transmitted; he meant that the individual was born with some defect in his blood-making organs which we did not recognize for years. An analogous condition was seen in progressive muscular dystrophy, in which the symptoms did not appear until after the lapse of a certain number of years. In going into the history of these cases of pernicious anæmia, we should not be content to learn that there had been no similar cases in the family, but we should try to find out about the health of the generation to which the patient belonged. Congenital defects should also be inquired after.

A Case of Tetany Dependent on Auto-Infection.—This case was reported by Dr. Andrew H. Smith. He said that in April of this year he was called by Dr. Bradley, of Ottawa, Canada, to see a patient of his in that city. The patient, a married lady about thirty-two years of age, with three children, had had fairly good health until about a year before her present illness. At that time she began to suffer from dyspepsia, which became more and more troublesome, and was marked by great acidity of the stomach and the formation of large quantities of gas. Her health and strength failed rapidly, and she developed marked insomnia. Two months before his first visit the first attack of tetany occurred. The contractures as described were confined to the hands and feet. The fingers were forcibly flexed into the palms, and the wrists extended and rotated outward to an extreme degree, causing intense pain. The duration of this attack was about an hour. Three other attacks occurred during the following two months. In some of these trismus was associated with the contractures of the hands and feet. In every case there were prodromal symptoms such as tingling, prickling, etc. There was also a sense of painful pressure in the epigastrium. On two occasions the pain attending the contractures was so great as to demand the use of chloroform. The paroxysms lasted from one to two hours, and were succeeded by great soreness of the muscles. For two or three weeks before Dr. Smith's visit the patient had been suffering from delusions and spectral illusions of a most distressing character. She thought she was away from home and was being very cruelly treated by her nurse, and that frogs, mice, etc., were running over the bed. She would cry out with horror, and these cries met the doctor at the door on his first arrival. Food of any kind excited nausea and attempts to vomit, which latter were ineffectual owing to the dilatation and malposition of the stomach. The resulting distress was extreme, and the misery of the patient was almost

indescribable. She was greatly emaciated, and too weak to bear her weight upon her feet. Sleep was almost out of the question, and the little that was obtained was at the expense of a free use of hypnotics. There was severe and persistent headache, with a burning sensation at the base of the skull. While there was little sleep, there was often a vacuous condition of the mind, rendering the patient unconscious of her surroundings. At times she would pass into a sort of revery in which food would remain in her mouth without her making an effort to swallow it. Her exhaustion was such that a fatal termination seemed to be near at hand. The cause of this condition had been recognized as auto-infection resulting from retention and putrefaction of food in a greatly enlarged and dependent stomach. The lesser curvature of the stomach was at the level of the umbilicus, and the lower border reached to a point midway between the umbilicus and the pubes. There was no history pointing to ulcerative action about the pylorus. Apparently the enteroptosis was the starting-point, the dilatation being consecutive. The gastric disturbance followed upon the birth of her last child about five years ago, and it was noteworthy that the abdomen never regained its shape after that event, but remained lax and somewhat pendulous. A plan of treatment was agreed upon, based upon the theory that the toxin was probably albuminous in its character and derived from the proteids in the food. The stomach was washed out twice a day, and the diet was so selected as to exclude as far as possible all nitrogenous substances. After each irrigation a pint of whey was left in the stomach, together with a tablespoonful of powdered willow charcoal and a scruple of salicin. In the intervals farinaceous food was given in small quantities, and later the yolk of an egg was added. Additional doses of salicin or other antiseptic were employed. High enemas of hot saline solution were given twice daily. A calomel purge was ordered, and this was repeated from time to time as required. Hyoscine hydrobromate, with moderate doses of sodium bromide, quieted the nervous excitement and procured sleep. Some degree of improvement was apparent very soon after this treatment was begun, and each day marked a decided advance. The improvement was first noticeable in the mental condition, which became quite normal at the end of a week. Strength was regained rapidly; in a fortnight the patient was about the room, and by another fortnight she was able to drive out. Only one setback occurred, which was about ten days after Dr. Smith's visit, when there were two attacks only a few minutes apart and quite severe. No tetany had been manifested since, though the premonitory prickling, etc., returned several times during the summer when the lavage had been neglected for some time. The use of hyoscine was continued for some two weeks with excellent effect, when it was found that the eyes were weak and watery. This condition was traced to the mydriatic effect of the hyoscine, and yielded readily to instillations of a one-per-cent. solution of pilocarpine. Great benefit resulted from the use of a tightly fitting belt, by which the stomach was held in a less unnatural position.

Since the above was written the patient had come on to New York, and at the present writing was under Dr. Smith's care. For some time she neglected the lavage, and ate pretty freely of animal food. The premonitory symptoms of tetany appeared again, and this led her to come to this city. In the few days since her arrival her condition had not improved, notwithstanding a resumption of the measures employed so successfully before. In view of the very serious nature of the tetany arising from gastric dilatation (the mortality being about seventy per cent.) the present situation was not reassuring.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, November 26, 1900.

GEORGE B. FOWLER, M.D., PRESIDENT.

The History, Aim, and Purpose of the Medical Society of the County of New York.—DR. FRANK VAN FLEET read a paper with this title. He said that the system of medical societies, of which this county society was a part, had been established since 1806, and was no new experiment. This organization had lived through many trials and vicissitudes, yet had continued to fulfil its proper functions. This society was part and parcel of the Medical Society of the State of New York, and what was said of one applied to the other, and to the society of every other county in the State. One of the functions of this organization was the dissemination and propagation of the knowledge of the science of the practice of medicine, but a more important function was the regulation of the practice of physic and surgery in this State, and the legislature had delegated to this society the burden of the enforcement of the medical laws of the State. The law of 1806, creating medical societies, had marked an epoch in the history of medicine in this State. It gave the societies so incorporated the right to examine students in medicine and grant licenses to practise. The State, by this act, created a special department which became an integral part of the machinery of the State. This relation between the State and the various county societies continued to exist for thirty-eight years with slight changes. In 1818 a law had been passed authorizing colleges to send delegates to the society, and ordering all practising physicians to connect themselves with the county societies in the counties in which they resided. In 1837 to 1839 the University of the City of New York and the Albany Medical College were authorized to send delegates to the State society. In 1844 a law had been enacted removing all the restrictions hitherto existing, and allowing all persons, without special qualifications, to practise medicine. It was strange, indeed, that at so late a date in liberty-loving America there should have been such intolerance and bigotry, that physicians differing from the majority of the profession in their therapeutic beliefs should have been not only ostracized but prevented from practising their calling. This was bad enough, yet there existed in the State and in the county of New York at the present time an organization founded and maintained for the special object of keeping alive such prejudices and such monstrous bigotry. In the early part of the century homœopathy had come as a welcome variation, and it would have been tried and discarded long ago had it not been for the intolerance of the advocates of the older methods of practice. Those who wished to practise homœopathy were expelled from their county societies, which was equivalent to excluding them from the practice of medicine. In 1846 the American Medical Association had been created with a view of securing better mutual protection among medical practitioners. It was preceded by the American Institute of Homœopathy in 1844. Both of these bodies had been established with the same general objects in view, and a bitter war had been waged between them. In 1882 the Medical Society of the State of New York, by a substantial majority, had abolished the code of ethics, thereby allowing its members the privilege of meeting any legal practitioner of medicine in consultation. The far-reaching effects of this action of the State society had probably been greater than many had at the time realized. The first effect had been to bring the warring elements together, and to lead them to see that their interests were more nearly identical than

they had supposed. This had led to certain medical legislation, and these laws now stood as a monument to the broad-minded policy initiated and carried out by the Medical Society of the State of New York. To gain the right to practise medicine in the State of New York to-day meant something—it meant that he who had gained this right had shown to an impartial board his ability to practise medicine properly. It made no difference who the candidate was, or from how many colleges he had graduated, he came before the State examining-board on an equal footing with all other candidates, of whatever school in medicine, to obtain his license to practise. The number admitted in 1899 was six hundred and seventy-one, while that in 1895 was four hundred and eighty-two. The result of the law had been a raising of the standard of requirements in this State, and an improvement in the teaching in the undergraduate schools. It was true there were imperfections in the present law, but they would be remedied very soon were it not for the enemies of the society, and particularly the enemies within its own ranks. There was an organization which had done, and was doing, its utmost to overthrow the Medical Society of the State of New York and its county branches—he referred to the New York State Medical Association and its county branches. This association, he stated, represented a principle which was antagonistic to the medical laws of the State of New York as well as to the spirit of the institutions of this State and of the United States. This principle was formerly upheld by the Medical Society of the State, and it resulted in the overthrow of the medical laws of the State in 1844. When the State society had refused to be governed by the code of ethics of the American Medical Association it had abolished this principle and had made possible the enactment of the present medical laws of the State.

The State society had no representation in the American Medical Association because it refused to be governed by the code of ethics of the latter association. Why was this? Because this code of ethics upheld a principle which was un-American, which was contrary to the teachings of the Constitution of the United States, and which was contrary to the dictates of humanity. The code of ethics has much to say about the dictates of humanity, but it ostracized from the pale of professional intercourse and consultation any person who believed contrary to what the association thought he ought to believe. This was contrary to the Constitution of the United States, which gave to every man the right to believe as his conscience dictated. When this code said that no one could be considered a fit associate in consultation whose practice was based on an exclusive dogma it denied to humanity intelligent treatment. Medicine was not a commercial calling, nor was it so narrow that its followers should allow themselves to be swayed by whims and individual prejudices. Surely no regular physician should hesitate to give the benefit of his knowledge to a patient who was being treated by one whose practice was founded on an exclusive dogma.

Continuing, the speaker said that in 1897 the legislature had been petitioned to grant the New York State Medical Association equal representation with the State society in the State board of medical examiners, but this had been refused by the legislature. The request had been renewed last year, when an effort had been made to secure a charter. The legislature had granted a charter, but had refused to allow the association to interfere with the medical laws. New York City now had on its hands a lawsuit, which, had not the legal authorities considered it unjust, the city would have settled before this. The suit had been brought nominally against the city, but it was really a final effort of the New York County Medical Association to compel the Medical Society of the County of New York to divide with it the work of enforcing the laws on medical practice. The law was very explicit in its statement as to what societies to consider its representatives in this matter, and it did not include in this list the New York County Medical Association. The section of the law providing for the collection of fines for violation of the law gave the county society the right to receive the fines in cases in which the complaint had been made by that society. The New York County Medical Association claimed that it had the right to collect fines under such conditions, and hence this suit. The comptroller had refused to pay over the fine, claiming that the law referred to the Medical Society of the County of New York. The attorney-general rendered a decision to the effect that the word "society" in the law could be made to include the New York County Medical Association. The comptroller refusing to be governed by this decision, the suit mentioned had been brought. Judge McAdam, in the supreme court, ruled that the New York County Medical Association had the right to collect such fines. The comptroller and the corporation counsel refused to abide by this decision; hence the case would soon be again argued, this time in the appellate division of the supreme court. Judge McAdam had evidently been greatly influenced in giving his decision by the fact that the New York County Medical Association had the right of representation in the American Medical Association, believing that by such connection the medical laws could be better enforced. This raised the important question as to whether it was desirable for the county society to be so related to the American Medical Association. While a national body, it was purely voluntary in its character, and was not, like the Medical Society of the State of New York, incorporated, or an integral part of the government. The Medical Society of the State of New York had not the migratory habit of the American Medical Association, but met annually at the State capital at the time the legislature was in session. It had done much to elevate the medical profession, and certainly should be represented in every national body, and would be represented in the American Medical Association, were it not for the code of ethics of the latter body, which the New York State Medical Society refused to endorse, and which even the members of the American Medical Association confessed nobody lived up to. When the American Medical Association agreed to allow each State to regulate its own affairs, and invited the Medical Society of the State of New York to send delegates to it, the unhappy breach which now existed in the profession of this State would be closed.

It was perhaps unfortunate that any medical society should be burdened with enforcing the medical laws, for it led to a widespread and deeply rooted suspicion that the prosecution of alleged illegal practitioners savored more of persecution. However, years of experience had enabled the county medical society to build up a system which made the detection of illegal practitioners of medicine comparatively easy, and the division of this responsibility would surely lead to confusion and to a lax enforcement of the law. A division of this work would also greatly increase the expense. The county society now employed legal counsel, paying therefor a salary of $1,000, and expending annually about eighteen hundred dollars in securing the necessary evidence. It might seem to some persons that the division of this work would distribute the burden, but this was not so, for most of the members of the New York County Medical Association were also members of the county society. What a spectacle was presented in this State with two county organizations having almost an identical membership,

yet supposed to be diametrically opposed in their guiding principles and beliefs! The New York State Medical Association had had seventeen presidents, eleven of whom were now living. Of these eleven, eight were members of county societies. How these gentlemen could reconcile this peculiar dual position was difficult to understand. The sole purpose of the State association was the overthrow of the State society, and it was due to their efforts alone that the breach still remained open between the Medical Society of the State of New York and the American Medical Association.

In conclusion, the speaker said if he had succeeded in demonstrating to any considerable number the necessity of caution in connecting themselves with organizations whose purpose was to destroy the influence and work of the Medical Society of the State of New York, and its branches, he would feel amply repaid for having written this historical sketch.

Notes on Influenza.—Dr. A. Jacobi read a paper with this title.

Gastro-Intestinal Form.—He said that in the gastro-intestinal form the tongue was usually heavily coated, and there were also loss of appetite and vomiting, or perhaps moderate diarrhœa and moderate jaundice. Frontal headache was very common. In some cases, on post-mortem, the patches of Peyer had been found enlarged and ulcerated in cases that had exhibited severe diarrhœa. In the circulatory system the heart suffered more than the blood-vessels. In many cases it was difficult to say whether it was the heart muscle or the innervation of the heart which was most affected, yet often it was plainly the latter. Bradycardia was more frequent in the young when suffering from influenza than from any other infectious disease, even typhoid fever. A disproportion between the pulse and temperature was very frequently noted. Even with a complicating pneumonia the pulse might be found comparatively slow. Syncope was not infrequent and sudden deaths were not unheard of. Acute dilatation of the heart could be occasionally diagnosticated; however, myocardial murmurs were not often noted.

Nervous Form.—The nervous form of influenza was quite frequently met with in later childhood and in adults. It ran its course with few local symptoms, and hence was less easily recognized in the beginning when it occurred in the very young. While there were nervous symptoms in every sort of infectious fever, influenza appeared to be mainly localized in the nervous system in a great many cases. Severe headache, excitement, delirium, semi-consciousness and coma, persistent insomnia, pains in the muscles about the joints, were all explained by this infection. Encephalitis, meningitis, myelitis, and neuritis were all observed in this class of cases. He had observed in infants suffering from influenza rigid contraction of the neck lasting for several days. He had seen a few cases of neuritis and neuritic paralysis associated with influenza. It was more probably a toxin than a microbe which caused the tedious convalescence from influenza. Almost every form of paralysis had been observed since influenza had been common among us.

Respiratory Form.—Bronchitis in the larger tubes was easily diagnosticated by the usual methods. When it affected the finer bronchi it gave rise to suffocation and cyanosis more readily than in the ordinary forms of bronchitis. The interstitial form was not met with by itself. Terminations in abscess, gangrene, and death were much more common during influenza epidemics than at other times. Complication with pleuritis, frequently suppurative, was especially common during an epidemic of influenza. Young infants were not so liable to an attack of influenza as older persons. In this respect they resembled old persons. When infected they lost weight rapidly. The temperature was not always high: indeed, it might often be subnormal, as in other forms of septic infection. As to this relative immunity of the young infant it was suggested that perhaps the nasal mucus had a bactericidal effect, or that the influenza bacilli might be stopped in the throat by the relatively large size of the tonsils. The onset was apt to be sudden and the prostration marked, but the temperature was very erratic. A few cases ran their course in a few days, but many patients suffered from angina, otitis media, and conjunctivitis. Accommodation paralysis and amblyopia were not unknown.

Prognosis.—The prognosis was not unfavorable if the patient was in good health at the time of the attack. Infants might die from enteritis. Altogether the immediate mortality was not very large, but indirectly the disease might prove dangerous, and was very often fatal on account of the respiratory diseases of adynamic type which were common sequelæ. Not infrequently influenza was the starting-point for tuberculosis. The prognosis should never be considered positively safe, for the physiological strength of the child's heart was no protection against the debilitating effect of the toxin of the influenza bacillus. Relapses were frequent, for there was no immunity, but, on the contrary, a seeming predisposition to subsequent attacks. The microbic cause might at one time attack the nervous system, and at the next the respiratory organs. The persistent cough should warn us not to make the prognosis too favorable. In his experience, nephritis had not been an infrequent occurrence after influenza. The diagnosis should not be made from the positive albumin test, which indicated all of the albuminoids. Microscopical examination of the centrifuged urine should always follow the chemical test, and would reveal nephritis in a respectable proportion of cases. Fortunately the nephritis which complicated influenza was not ominous, but it should lead the physician to be cautious in making the prognosis.

Prophylaxis.—The communicability of influenza was extraordinary. It should be kept out of sanatoria by strict isolation during an epidemic of influenza. Closing schools would be futile as a prophylactic measure because the little ones would contract the disease outside of the schools. If nursing mothers were sick with influenza the suckling infant should be brought to the mother only for nursing. A good preventive was to wash out the throat with water slightly acidulated with hydrochloric acid. Medicinal preventives had been recommended—cod-liver oil, calcium sulphide, and quinine. His experience with them had been very small and unsatisfactory.

Treatment.—There was no specific for influenza. A purgative dose of calomel should be given, as the bowel was the principal point of attack in very young infants. The patient should be kept in bed in a room having a temperature of 70° F. or a little higher. The diet at first should be light. Alcohol and other stimulants were required only in selected cases, and in this respect influenza differed from certain other infectious diseases, notably typhoid fever and diphtheria. If the temperatue was high, cold water was not indicated, either as a bath or as a pack. The irritative cough was apt to be aggravated by cold water. When there were much muscular pain and restlessness a warm bath was often beneficial. A hot bath, except a very short one in the event of threatened collapse, should be avoided. Influenza pneumonias did better with warm than with cold packs. In the German collective investigation reports some observers praised quinine highly, while others expressed great disappointment with its action. When the vomiting was severe, rectal alimentation was indicated. Peptones

and liquid albumins were readily absorbed in the colon, which even in the smallest infant was made accessible by raising the hips, but not raising the irrigator more than a foot above the anus. Dextrinized starch would add to the nutrient value of the enema. The best relief from medicines was secured by the use of morphine. A tablet containing gr. $\frac{1}{60}$ of morphine should be placed in the mouth of a child from two to four years old, there to be absorbed, or one-half drop to two drops of Magendie's solution might be given in the same manner. The treatment of the symptom fever offered no hope of shortening the disease, but it contributed to the patient's comfort and did not interfere with recovery. To be satisfied with depressing temperature was a great mistake, but to allow influenza or any other disease to run its course with no attempt to combat the obviously injurious effects of fever on the system was equally reprehensible. Continuous fever, even though moderate, should not be allowed to run indefinitely without any attempt to check it. Nervines and analgesics were valuable aids to bathing, or as substitutes for baths, and they usually increased the comfort and favored metabolism. He had formerly asserted that acetanilid should be preferred among the poor, because of its low price; antipyrin when solubility was important, and phenacetin was preferable to either when it could be given by the mouth, because of its superior action on the brain and on the skin. Antipyrin, when employed during normal conditions, increased the pulse and blood pressure; hence it was contraindicated in hæmoptysis. It was not a nervine, as it acted chiefly upon the blood-vessels. To get the antipyretic effect the dose should be repeated in two hours. In general, its action was favorable. Phenacetin resembled acetanilid, but was milder. The dose should be gr. ¼ to ½ for infants and young children. Salipyrin should be given in twice the dose of antipyrin. It was usually better borne than antipyrin by neurotic persons. In using these drugs it should always be borne in mind that influenza showed a strong tendency to prostration and heart debility, and hence when there was any indication of such an occurrence these remedies should always be guarded by the coincident adminstration of caffeine benzoate or salicylate. This was preferable to the use of alcoholic stimulants. When caffeine unpleasantly excited the brain it should be replaced by camphor in doses of gr. iss.–vi. Camphor was soluble in four parts of sweet almond oil. A most useful though little used cardiac stimulant was Siberian musk. The ten-percent. tincture should be given in doses of five to ten minims every half-hour for eight or ten doses. This remedy had many times tided his cases over desperate crises.

Dr. Francis J. Quinlan urged that general practitioners, when treating influenza, should give due attention to its effect on the respiratory passages, thus preventing many complications, and shortening the period of convalescence.

Dr. Wickes Washburn said he felt positive that an attack of influenza could be cut short by washing out the bowel and abstaining as far as possible from all food for the first two days. When this was not practicable, broths should be given in preference to milk. Thirst could be assuaged, and the renal function stimulated, by frequent small doses of citrate of magnesia.

Carbonic-Acid-Gas Douche in the Nose.—Dr. A. Rose advocated the use of the carbonic-acid-gas nasal douche in cases of influenza. This gas caused anæsthesia, and at the same time hyperæmia, but its application greatly facilitated the discharge of mucus. The application was pleasant and a few applications only were necessary to give marked relief. This improvement was not merely temporary, for, according to his experience, this use of the carbonic-acid gas acted as a tonic to the nose, and its good effects often continued for months or years. The treatment was absolutely harmless, and could be most readily applied, even among the ignorant.

Dr. Mennen remarked that although he had devoted many years to the study of infectious diseases, he felt sure that little was known as yet about the true nature of influenza.

Vaccine Lymph a Potent Alterative.—Dr. H. Holbrook Curtis spoke of the effect of vaccine as an alterative. He said that at the time that Koch's lymph had attracted so much attention, several articles had appeared on the effect of the subcutaneous injection of vaccine lymph in cases of phthisis. The speaker said that he had since tried this treatment, using a dose of 1 mgm. of the board-of-health vaccine, and injecting it into the muscles of the back. The results had seemed to him marvellous, and further study had led him to look upon this lymph as a powerful alterative. He had treated a great many cases of influenza with good success, yet had made no use of the coal-tar derivatives. He was a firm believer in aconite, being of the opinion that it acted like a cardiac stimulant by diminishing the work the heart was called upon to do.

Dr. Elmer Lee said that he regarded these epidemics of influenza as merely a periodic welling-up of impurities, principally in the blood and lymph systems. The eliminative treatment he considered the ideal. This consisted in feeding the patient for four or five days almost exclusively on water, while the bowel was washed out, and the patient received frequent baths. Very little medicine was required. This simple treatment would get most patients well in an astonishingly short time. Morphine might be used to relieve the distress, but it should be given in very small doses, preferably by dropping half a grain or one grain into a glass of water, and giving a teaspoonful of this mixture at short intervals until the desired relief had been obtained.

Committee on the Certification of Milk.—Dr. H. D. Chapin said that this committee was carrying on its work with energy, and had been greatly encouraged by the large and interested audience that had assembled in response to the invitation of the committee. Many prominent dairymen had been present and had shown a desire to co-operate with the medical profession in securing the certification of milk of proper standard.

Tax on Legacies.—Dr. A. Jacobi introduced the following preamble and resolution, which were unanimously adopted by the society:

Whereas, The War Revenue Act of 1898 laid a tax on legacies of educational, charitable, and religious organizations; and

Whereas, Such organizations and institutions are, and should be, considered as the most solid pillars of our intellectual and moral culture; and

Whereas, The crippling of their means, always insufficient for reaching their highest legitimate aims, is very great as a result of this tax, as they are so largely dependent upon individual generosity and good will;

Be it Resolved, That the Medical Society of the County of New York respectfully petitions the Congress of the United States to repeal such parts of the revenue law of 1898 as enact a tax on legacies of educational, charitable, and religious institutions and organizations.

Copenhagen is reported to be suffering from an epidemic of what the cable calls "typhus" fever, twenty new cases having been reported in one day last week. Whether the disease is typhus abdominalis, which we call typhoid, or actual typhus is not stated.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNÆCOLOGY.

Stated Meeting, November 22, 1900.

J. Riddle Goffe, M.D., Chairman.

The Abdominal versus Vaginal Hysterectomy for Cancer of the Uterus.—Dr. W. R. Pryor opened the discussion on this subject, excluding a consideration of cancer of the uterine body in connection with his comparison of statistics. He said that enough had been learned about this disease to allow of the laying down of certain fundamental principles. All operations for uterine cancer should proceed with a due regard to the manner in which cancer spread and recurred. Recurrence after operation was seen in the perimetric tissue in ninety-six per cent. of the cases. A successful operation must remove not only the uterus and adnexa but a considerable portion of the vagina and adjacent glands. These glands were in three groups, viz., (1) the obturator glands, (2) the glands situated near the bifurcation of the common iliac, and (3) the glands at the utero-sacral folds. The removal of the obturator glands was the most important. Vaginal hysterectomy was, therefore, only a partial and incomplete operation for cancer in all but a few cases of cancer of the uterus. The next principle was that the immediate mortality must not be so high that one dared not depart from mere palliative measures. A collection made abroad of thirty-one hundred and fifty-five vaginal operations gave a mortality of nine per cent., and he had himself shown that the mortality from the abdominal operation in America was 11.8 per cent. Abdominal hysterectomy by progressive ligation was not a proper operation for cancer. The next fundamental principle was that in the act of removal all possibility of infecting the wound by either cancer cells or by the particularly septic contents of a cancerous uterus must be avoided. This accident could be escaped whether the operation was done through the vagina or the abdomen. The first step in either operation should be a thorough curettage and a cauterization, which disinfected the cancerous mass, and closed, to a certain extent, the mouths of the absorbents. The fourth principle was that in the removal of the cancerous uterus as little violence as possible must be inflicted upon the growth and upon the surrounding structures. The preliminary charring of the uterus aided in this, but it was advisable to exercise preliminary hæmostasis in the removal of the lymph glands. This could not be done in vaginal hysterectomy. He believed that in cancer of the cervix the sum total of human life saved by palliative methods was far greater by vaginal hysterectomy. In all the great clinics about seven per cent. only of all the women coming with cancer of the uterus were in the operable stage. The speaker said that every single essential could be carried out fully in the abdominal operation. The foregoing statements were given in order to show why vaginal hysterectomy had failed, and what was required in an operation which should give satisfaction.

Dr. H. J. Boldt continued the discussion. He said it was impossible, in his opinion, to advocate either operation in all cases. Personally, he thought that only in exceptional instances should abdominal hysterectomy for cancer be performed until we were in possession of facts proving its superiority over vaginal hysterectomy in ultimate results. Cancer of the uterus should be divided into three varieties, viz., (1) cancer of the infravaginal portion of the cervix, (2) cancer of the supravaginal portion of the cervix, and (3) cancer of the uterine body. This division was dependent upon the variations in the extension of the neoplasm to the neighboring structures. We knew that cancer beginning in the mucous membrane covering the vaginal portion of the cervix had a decided tendency to encroach upon the vaginal mucosa. Cancer of the supravaginal portion had a tendency to extend upward into the uterine body. Cancer beginning in the body of the uterus not infrequently extended downward. It must be conceded that the blood-vessels were affected only in the late stages of cancer and that metastasis seldom occurred through their medium. The lymphatics were the usual means of the extension of the disease. Abundant experience had shown that the glands were not usually invaded by the disease until late; even in advanced stage of cancer of the uterus the lymphatic glands were not constantly invaded by cancerous elements. Experience had also shown that recurrence after radical operation seldom took place in the glands. Vaginal hysterectomy permitted a smaller opening of the peritoneal cavity; it usually took less time to perform; convalescence was much more rapid; the abdominal wound, with its occasional ill consequences, was avoided, and the direct mortality was less. He had always practised extirpation of the parametria as far as possible, and exsected a large portion of the upper part of the vagina. The advantage of abdominal hysterectomy was that it permitted more extensive removal of the lymphatics and retroperitoneal glands. He doubted, however, whether it would give a larger percentage of recoveries, because of the frequency with which the lymphatics were not involved even in the late stages. Time alone could settle this question.

Dr. J. E. Janvrin opened the general discussion. He said that his own ideas concurred very strongly with those expressed by Dr. Boldt. He believed that at first all cancerous disease was local, and was generally the result of some injury. This was particularly true of cancer of the cervix, and hence, in cases coming early, before there was any extension of the disease into the lymphatic glands and into the parametria, the proper course to pursue, in his opinion, was to perform vaginal hysterectomy. These cases were seen now quite frequently, probably because the profession at large diagnosticated uterine cancer at an earlier stage than formerly. His own successes thus far, counting cases dating back eighteen years, comprised fully one-third permanent recoveries. They were early cases, and hence, in a certain sense, might be said to have been selected cases. If the disease had extended some distance down the vaginal wall this made no difference, because it was very easy to extirpate a considerable portion of the vagina. If examination showed pretty extensive disease, the uterus being large and fixed, and there was reason for believing that the patient was suffering from the cancerous cachexia, he always felt that the operation, however performed, was purely palliative, and that each surgeon must exercise his individual judgment as to which method would give the greater relief. He was of the opinion that it was better to operate in such cases because the pelvis was closed in from below, and the vagina from above, and the recurrence of the disease did not bring with it the offensive discharge and the hemorrhages which occurred if the uterus was simply curetted and left.

Dr. William M. Polk said that his own experience in this field had been so ghastly that he doubted if he could add much of material value to this discussion. Of all the cases of cancer of the uterus upon which he had operated he had cured, he believed, only one, and all patients had died from the recurrence of the disease. He was of the opinion that all of the operations hitherto offered for cancer of the uterus were of but little value, being nothing more than an effort to make the patient's condition somewhat more tolerable.

He had searched for some more extensive and more radical method of operating in cancer of the uterus, but even the more recent extensive operations had not seemed to him to hold out much encouragement. He preferred the more open field of the abdominal route, because he had not been able to do a sufficiently extensive operation through the vagina, though well knowing the seriousness of the abdominal operation.

Dr. W. Gill Wylie said that his experience had been that in young women the disease was easily recognized, but was rapid in progress and difficult of control. In older women the onset was more insidious, but the disease spread less rapidly than in younger subjects, and was more amenable to operation. If such cases came to the surgeon before they had been disturbed by active treatment, it was possible to attain a considerable degree of success. It seemed to him very reprehensible to take away a piece of tissue for examination, and then allow an interval of two or three weeks to elapse before doing a radical operation. He could count among his successes patients who had been operated upon from sixteen to twenty-five years ago and were still alive. In his first sixty or seventy cases he had, in almost every instance, operated through the vagina, at first with the ligature, and later with the forceps. The condition of the lymphatics and surrounding tissues had more to do with a successful result than the particular method of operating. When he had been able to feel lymphatic glands in the broad ligaments he had rarely, if ever, secured a good ultimate result, no matter how extensive the operation or the method selected. He firmly believed that the only method of treatment was by some operation designed thoroughly to remove the disease. It had seemed to him at times that the occurrence of suppuration had insured against a recurrence of the cancer.

Dr. Ramsay, professor of gynæcology at Yale, was invited to take part in the discussion. He expressed his belief that it was a mistake for one to adhere to any one operation in all cases of cancer of the uterus. In the greater number of cases he was of the opinion that the suprapubic method was the preferable one, though the combined operation might perhaps be found in the future to be still more generally useful. Up to the present time enough cases had not been treated by the combined method to enable one to decide this point. It had been discovered lately that enlargement of the lymphatic glands did not necessarily mean that cancer had invaded them; the increase in size was sometimes the result of mere hyperplasia of the glandular tissue.

Dr. A. Palmer Dudley said that the field under discussion was the only one in gynæcology in which he would recommend a single operation for all cases, and that operation was the combined one. No two cases of cancer of the uterus were exactly alike, but the object in each instance was to remove the disease as thoroughly as possible. By either the abdominal or the vaginal route one was apt to leave some of the disease. There was no more shock from the combined operation than from the suprapubic operation alone. In addition to this method of operating he had derived aid from the hypodermic injection of an alkaloid, but he was not in a position at the present time to go further into the details of this mode of treatment.

Dr. W. Evelyn Porter said that at first he had been a very strong advocate of the vaginal route, but had subsequently come to look upon the combined method as the best of all. He believed when there was extensive glandular involvement no operation would effect a cure. However, when there was extensive involvement of the vagina and any operation must be merely palliative, he would select the vaginal route.

Dr. Pryor said that his reason for selecting the abdominal route was that it enabled one to make the dissection of cancer in healthy tissue, and after all the blood supply had been cut off. He personally preferred to ligate the internal iliac arteries and also the obturator artery. The object of this preliminary hæmostasis was not so much to secure a dry field as to enable the operator to reach glands which were practically inaccessible if this procedure were omitted. Vaginal hysterectomy seemed to him an illogical method of dealing with cancer of the uterus.

Dr. Boldt, in closing the discussion, said that as he understood it Dr. Pryor refused to wait for the ultimate results from vaginal hysterectomy. All were agreed that the glands were involved late in the disease, and he could see no reason for operating at all if these glands were extensively implicated, because the patient would surely die. All must recognize that the results of operation in cancer of the uterus were, on the whole, quite poor, and few surgeons, he thought, would be willing to claim the exceptionally good results that had been mentioned in this discussion. In cases of supravaginal cancer occurring in young women he would expect a larger proportion of good ultimate results from the abdominal operation; but, on the other hand, if the patients were more advanced in years he would look for better results from the vaginal operation.

SECTION ON MEDICINE.

Stated Meeting, November 20, 1900.

John H. Huddleston, M.D., Chairman.

The Early Recognition of Typhoid Fever.—Dr. J. K. Crook presented this paper. He said that there were some cases labelled typhoid fever which showed none of the symptoms of typhoid except a moderate and atypical range of temperature, with loss of appetite and strength. Not infrequently the patient with typhoid fever in the early stage called at the physician's office complaining of troublesome headache, chilly sensations, and aching in the muscles. The tongue was usually dry, the pulse somewhat raised, and its frequency easily increased on slight excitement or exertion. Even at this early period there would usually be found in the afternoon a rise of temperature of one or two degrees. Gurgling in the right iliac fossa possessed no diagnostic significance in typhoid fever, because it was often present in cases of ordinary diarrhœa or even in perfect health. There was nothing about these symptoms to warrant a diagnosis of typhoid fever, but enough were present to put the physician on his guard, and he should insist upon seeing the patient twice daily for two or three days, or if this were impracticable, should instruct him in the use of the clinical thermometer. After a day or two the symptoms first observed would be more marked, and the prostration and dull expression of the face would be more noticeable. Perhaps at this time it would be possible to detect on careful percussion an enlargement of the spleen. If malaria was suspected, an examination of the blood or the result of the administration of full doses of quinine would clear up this aspect of the case. By the end of the first week there would be so much prostration that the patient would be perfectly willing to remain in bed, and most likely the pulse would be soft, rapid, and perhaps dicrotic. The temperature would possibly reach a maximum of 104° or 105° F. If carefully sought for, the speaker said, he believed the presence of a typhoid eruption would be found in a larger proportion of cases than was usually stated. Two or three spots were as diagnostic as two or three dozen, though, of course, not so easily detected. As early as the seventh or

eighth day the diazo reaction of Ehrlich was obtainable in the urine. It was a sign of much negative value, but it should be remembered that it occurred in many other conditions, notably in measles and acute tuberculosis. In his experience this sign had never failed. If an examination of the blood showed the Widal reaction, the diagnosis was positively established.

The Treatment of Typhoid Fever at the New York Hospital.—Dr. Frederick L. Keavs presented this paper (see page 851).

Practical Home Methods of Bathing in Typhoid Fever.—Dr. S. Baruch discussed this phase of the subject. He said that the first impression of cold upon the skin was the so-called shock; it was really a physiological irritant. The impression lasted a longer or shorter time, depending upon the method of procedure and its duration. The friction stimulated the contracted arterioles to dilate again, and performed the important normal function of propelling the blood, thus keeping up a proper peripheral circulation. The latter was usually so crippled in typhoid fever that the heart was compelled to beat faster and more forcibly. By the proper use of cold water the pulse diminished in frequency and gained in force. The skin assumed a rosy hue because its arterioles had been dilated in a tonic fashion. The countenance lost its apathy, the respirations were deepened, and the kidneys were aroused to renewed activity. Friction should always accompany the cold-water treatment—a fact which even at this late day needed reiteration and emphasis. As an illustration of how the cold-water treatment should not be applied in typhoid fever the speaker mentioned the abdominal ice coil, still so popular with many physicians. This was a direct violation of the fundamental principle of all hydrotherapy, that cold applications must be accompanied by frictions. In home practice the ablution was the simplest procedure. The patient was stripped, a blanket placed underneath him, and first the back, and then the anterior surface of the body treated to the ablution. It should be given with considerable friction, the temperature of the water being reduced from time to time until the temperature reached 60° F. The abdominal compress was another useful method of applying cold water. This consisted of three folds of towelling wrung out of water at a temperature of 70° and applied snugly, being covered with thin flannel. It should be renewed hourly. When the temperature persisted in remaining at 103° or above, the towel bath was appropriate. A towel was dipped into water at 85° F. and laid dripping and smooth over the entire back. Water at 70° was dipped up with a cup and poured on the upper left part of the back, and then this part was rubbed with the hand. This was done three times, and then the other parts of the back were successively treated in the same way. The water on the sheet was mopped up with a sponge, and then the anterior parts were similarly treated, care being taken not to use pressure over the iliac region. The temperature might be reduced five degrees each time until the temperature of the water for the towel reached 60° and that in the cup reached 50°. The "sheet bath" was still more potent, and was very useful when objection was made to the full bath, or the latter was impracticable. An old linen sheet or tablecloth should be dipped in water at 90°, and wrung out very lightly. The patient having been wrapped in this, water at temperature of about ten degrees lower should be poured successively upon different parts of the body, and each part rubbed with the hands until it no longer warmed up. The typhoid-fever patient should be given internally from four to six ounces of water at 40° every two hours, and this should be alternated with the same quantity of milk.

Giaourdi; a Sterilized Fermented Milk Preparation Used in Greece.—Dr. Achilles Rose read a paper on this article of diet, which, he said, was of decided value in cases of typhoid fever and gastric ulcer. Milk was boiled for an hour under constant stirring until it became of a certain thickness, and then the ferment was added. This ferment was made by the Greeks as follows: A dry fig was soaked over night in ℥ xxv. of water, and the next morning a few drops of lemon juice were added and a slight trace of rennet. The result was a smooth, semi-solid, easily digestible milk food. In the months of August and September giaourdi was not made in Greece. After the ferment had been added to the milk the temperature of the product must be reduced to 45° Celsius. The speaker said that he had given this food in cases of gastric ulcer, and the patients had enjoyed it very much. In one case in which there was commencing stenosis of the pylorus, kumyss and matzoon had been tried, but giaourdi had been preferred by the patient.

Dr. E. Quintard said that he had used giaourdi in fifteen cases, and had found it exceedingly useful. He had used it in cases of neurasthenia in which even kumyss and milk seemed to distend the stomach. It was in these cases that giaourdi seemed to act especially well. He had also tried it with satisfaction in a case of pyloric stenosis. The great value of this article of diet was best shown by the fact that it had seemed to be superior to even those most excellent foods, kumyss and matzoon.

Dr. Helen E. Correll-Loewenstein said that she had examined this food for alcoholic fermentation, but had not found it present. She had tried various experiments with it, and had come to the conclusion that there must be some special ferment in the fig. She recalled that once while travelling in Switzerland a farmer had told her that he had a secret in the manufacture of cheese. Inquiry had shown that this secret consisted in using, in addition to rennet, a watery solution of fig. The speaker said that she had curdled some milk with fig, and had found that it produced a very smooth, soft curd.

Dr. Max Einhorn said that the well-known farmer's food, called "bonny-clabber," prepared from curdled or sour milk, was very much like giaourdi except that the latter tasted a little sweeter. It was an admirable food, and for its preparation only required that the milk be placed in a jar and allowed to stand for three or four days. This curdled milk was found to keep well for a long time. It was used by the peasants of Russia for the manufacture of cheese.

Dr. Rose said that giaourdi was very different from ordinary bonny-clabber or sour milk. The latter contained a great deal of lactic acid, which would not be tolerated by some sensitive persons, though they could retain giaourdi.

Gastro-Intestinal Diseases at the Paris Congress.—Dr. James J. Walsh read this paper.

Gastric Ulcer.—He said that gastric ulcer became a formidable complication in many infectious disorders. Ulcers having the characteristics of gastric ulcers occurred only in those parts of the digestive tract where there was free acid. Ulcerative lesions below the pancreatic duct occurred very rarely, and were of a superficial character, quite different from the deep erosion which characterized the gastric and duodenal ulcer. Gastric ulcers, therefore, were probably due to self-digestion, though the cause of this self-digestion was yet in dispute. It was worthy of note, in this connection, that those predisposed to gastric ulcer were just the ones in whom there was apt to be a gastric hyperacidity. Acute gastric ulcer seemed to be a pathological entity. The affection occurred most commonly in young women leading a sedentary life. Its presence was often announced by the occurrence of hemorrhage. In a certain number of cases of acute

gastric ulcer pure cultures of the pneumococcus had been found, although pneumonia had not been present. Another form of gastric ulcer occurred in connection with appendicitis. In France it had been described under the title of "appendicitis with black vomit." It was surprising that in the face of such extensive literature on appendicitis in this country no mention should have been made of this association of appendicitis and acute gastric ulcer. Patients who were anæmic or who were suffering from infectious disorders should be given remedies tending to reduce the gastric hyperacidity, and these persons should be warned against swallowing coarse food, or food before it had been thoroughly masticated. Gastric crises, the speaker said, were now known to occur in many other affections than locomotor ataxia. A striking feature of the discussion on gastric ulcer at the Paris congress was the general trend of opinion in favor of surgical intervention. Old ulcers and their scars were especially liable to be the seat of carcinoma, and this constituted one reason for advocating operation.

Olive Oil in Painful Affections of the Stomach.—A number of German observers had called attention to the value of olive oil in certain painful affections of the stomach. From three to ten ounces of the oil were given in the twenty-four hours. It had been found especially useful in cases of gastric ulcer. It had been stated at the congress by one speaker that morphine was contraindicated because it was excreted largely through the stomach, and this led to an increase of the gastric acidity. However, atropine could be used with benefit.

Muco-Membranous Colitis.—This disease seemed to have become much more frequent in recent years, probably because of the keen competition in all walks of life. Another alleged cause was the greater prevalence of the habit of taking irritating laxatives. The disease was chiefly seen in nervous, high-strung individuals. The nervous element seemed to be the most important factor in its etiology. When the disease occurred in young men it was almost always in connection with sexual neurasthenia. From the fact that appendicitis was scarcely ever associated with muco-membranous colitis it had been argued that the latter was not truly an inflammation—it was more probably a nervous disorder. The symptomatology consisted in the presence of glairy mucus in the stools, usually preceded by constipation and followed by pain. As soon as the neurotic symptoms subsided the mucous colitis rapidly improved, and ultimately disappeared. The treatment should be directed toward the underlying neurotic conditions.

Prognosis in Gastric Ulcer Good without Operation.—Dr. Einhorn said that he certainly believed that the gastric juice played a prominent part in the formation of gastric ulcers, but it was not the only factor. Cases had been reported of absence of the gastric juice, and yet at operation gastric ulcers had been accidentally discovered. He had seen one such case himself. Dieulafoy had spoken about infectious diseases in which there were almost imperceptible erosions of the stomach, and yet they had been sufficient to cause serious hemorrhage. Dr. Einhorn said that he could not agree with Dieulafoy that severe hemorrhage originated in such insignificant erosions, and said that the hemorrhages and even the deaths which Dieulafoy attributed to these erosions were really, in his opinion, caused by the concomitant infectious disorder. His opinion was that seventy-five per cent. of cases of severe gastric hemorrhage ended in recovery without operation, even when the condition appeared to be exceedingly grave. The risk from the operation was usually just as great as the danger from the disease, and hence it was an exceedingly difficult matter to decide as to whether or not an operation should be undertaken. As a rule, he did not think the mere occurrence of a hemorrhage from the stomach, even though a severe one, justified one in operating. Even when there was beginning stenosis of the pylorus he was in favor of not operating until it became evident that enough nutriment could not be introduced to sustain life. He had taken this position because twenty-five per cent. of his patients with benign stenosis of the pylorus who had been operated upon had succumbed. Regarding mucous colitis, he expressed the opinion that it was a purely neurotic disorder. The diagnosis of membranous enteritis rested upon the finding of small pieces of mucus in the stools. It was not really an enteritis.

Dr. F. F. Ward said that he had often wondered if gastric ulcer might not itself be the cause of hypersecretion, its presence giving rise to irritation and, in this way, to increased secretion of gastric juice. He had not been able to bring himself to believe that the hyperacidity was the cause of the ulcer. Reference was made to a case which had given all the typical symptoms of ulcer. It had proved very obstinate to treatment, and as the man's health was steadily failing an operation had been undertaken. Gastro-enterostomy had been performed, and recovery had been uneventful. At the operation a tumor had been felt under the liver. Six weeks later the abdomen had been opened again with the intention of removing this tumor, but then none could be found. It was supposed that the tumor felt at the first operation had been produced by contraction at the pylorus. For eight months after the operation the man had done exceedingly well; then an examination had shown an almost complete absence of gastric juice. About one year after the operation the man had been seized in the night with severe abdominal pain. A diagnosis of perforation had been made, but death had occurred before an operation could be done. At the autopsy, the stomach had been found adherent to the abdominal wall, and there was a perforation through the stomach at that point, where there was also quite a large malignant growth. Hemorrhages from the stomach sometimes arose from anæmic conditions. A case illustrating this point was quoted, in which at autopsy no ulcer of the stomach or of the duodenum could be found. He agreed with Dr. Einhorn that in most cases of gastric hemorrhage medical treatment should be preferred to surgical measures.

Dr. Quintard said that the exulceration of Dieulafoy was so minute that it required examination with a magnifying-glass to detect it. The severe hemorrhage reported as having come from such a minute ulceration had been explained by supposing that the ulceration had involved a capillary only to such an extent as to hold the rent in it open, and so allow of the profuse bleeding.

Diseases of the Mastoid Process.—Dr. G. H. Cox, in the *Maritime Medical News*, October, states that there are two signs which are characteristic of mastoid involvement and which, when present, are diagnostic. They are: (1) Tenderness upon pressure and percussion over the antrum or tip of the mastoid. Taking care not to move the auricle or meatus, we press firmly with the thumb over the regions mentioned, comparing the effects with those of similar pressure on the opposite healthy process. (2) The second sign, namely, a bulging or sagging of the postero-superior wall of the meatus at its innermost extremity, is the most characteristic sign of the disease. It is boggy and tender to the touch, and may be considered absolutely indicative of pus in the mastoid. A third sign of value frequently found in these cases is a bulging of the postero-superior quadrant of the membrana tympani.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending December 1, 1900:

	Cases.	Deaths.
Tuberculosis	221	137
Typhoid fever	110	21
Scarlet fever	117	2
Measles	95	2
Diphtheria	244	41
Laryngeal diphtheria (croup)	14	11
Cerebro-spinal meningitis	0	1
Varicella	26	0
Smallpox	34	0

The Cost of Running a Big Hospital in London.—"Always crying out for money?" said a gentleman connected with the administrative department of a great hospital, echoing the chiding remark made to him by the writer. "Of course we are always crying for money, more money, and simply because there is always a crying need of money in an establishment like this. I am often surprised at the lamentable ignorance people evince upon the subject of hospital finances; not one person in a hundred seems to have the remotest idea what it costs to run a big institution like this. I heard a city man tell another a few days ago that this hospital had an income of nearly £20,000 [$100,000]. He seemed astonished at the largeness of the sum. As a matter of fact, the income of this hospital is more than twice that amount, and yet it always has a deficiency on the balance sheet, and a precious heavy deficiency to boot. In round figures this institution costs between £70,000 [$350,000] and £80,000 [$400,000] to run. There are a hundred and one expenses which a stranger would never expect. You will hardly credit it, but we pay over £1,000 [$5,000] a year for milk alone, while eggs cost us from £300 [$1,500] to £400 [$2,000] a year. Our meat bill runs between £1,500 [$7,500] and £2,000 [$10,000], and that is quite exclusive of poultry and fish, which cost an additional £800 [$4,000]. A mere item like butter and cheese runs away with over £700 [$3,500] a year; vegetables and flour taking about £600 [$3,000] or £700 [$3,500]. It may seem strange to you that while milk costs us such a large sum alcoholic liquors rarely cost more than £250 [$1,250] in the course of twelve months. That practically exhausts the list of provisions, though you must understand the items I have mentioned are those things consumed by the patients; the boarding of the staff of medical officers and nurses is treated as a separate account, and adds an extra £3,000 [$15,000] or £4,000 [$20,000] to the total bill for provisions, which usually exceeds £10,000 [$50,000] per annum. Drugs, disinfectants, and chemicals usually cost us about £2,500 [$12,500], while dressings and instruments swallow up approximately £3,000 [$15,000]. Altogether the dispensing and surgery departments, exclusive of salaries, involve an expenditure of about £6,000 [$30,000]. I mentioned salaries, which is always a heavy item; £10,000 [$50,000] would not cover it. The nurses get some £4,500 [$22,500] divided between them during the twelve months; the dispensers between £900 [$4,500] and £1,000 [$5,000], and the medical staff £2,000 [$10,000]. An additional £3,000 [$15,000] is required to pay other salaries which I cannot classify. Of course you will understand that I am giving you round figures, and that when I say simply ordinary repairs made on the premises cost about £5,000 [$25,000] you must take it that I do not guarantee to be within a couple of pounds of the exact sum—but I may be, as I am in other figures, under- or over-estimating by £50 [$250] or £60 [$300]. Lighting and heating are costly, and the £3000 [$15,000] which it usually entails will probably be greatly exceeded this year owing to the increase in the price of coal. Our laundress receives £1,700 [$8,500] from us, and the tax collector £2,500 [$12,500]; £800 [$4,000] goes in printing, stationery, and stamps. But though I have not been more than half through the list of expenses, I think I have said enough to show you what an enormous amount of money is required to keep a hospital going for twelve months. Let me just say this: The eighteen largest items on the expenditure side of our balance sheet for last year amounted to the very respectable total of £68,500 [$342,500]. Think of that—write it down on a piece of paper, and you will not complain that hospitals are 'always crying for money,' without the best reasons."—*Tit-Bits.*

Medical Men and the Morphine Habit.—The London *Lancet*, October 27th, has an article on this much-vexed question, taking as its text an article on morphinism among physicians which appeared in the *Medical Temperance Review* for October. It may perhaps be remembered by our readers that Dr. Crothers, of Hartford, Conn., about a year ago gave some statistics, as well as delivered himself of some very decided opinions bearing on this matter, which gave rise to somewhat heated discussions, and which were commented upon editorially in the MEDICAL RECORD. The *Medical Temperance Review* would seem to hold almost similar views upon the morphine habit as does Dr. Crothers, but the writer in *The Lancet* is by no means in agreement with them and says: "If we are to credit the writer the habit of taking opium and allied drugs is more or less prevalent among six to ten per cent. of medical men. The statement is a vague one and no precise data are advanced in support of it, though the reader is referred to a former report dealing with the subject. It would be better for all purposes if a paper of this kind, which contains only the most general assertions, were elucidated by verified details; lacking these its value cannot be estimated or even recognized. It would be idle to deny that medical men, like all other men, are occasionally liable to propensities which do not make for their advantage and from which not even a knowledge of the action of drugs can always deliver them. On the other hand, indefinite assertions, like those contained in this brief paper, cannot be accepted without those proofs which are absent from it. That accidental opium poisoning has repeatedly cut off a useful professional career is unfortunately true. But a morphine habit which controls one in every ten or twenty men is certainly not known to exist in the medical profession. Such a habit, if it does exist, must be quite exceptional. It is probably unknown among practitioners engaged in active duty. We observe that the writer above mentioned speaks of the morphine habit as if it were merely a disease and nothing more. It has become customary with many persons to refer to this and other aggravated forms of self-indulgence in similar terms. They are regarded as vices which have ceased to give pleasure—as master passions which are hated but which will not be denied. Against this tyranny the will is supposed to have lost its power of resistance. There are doubtless cases of habitual excess, the character of which is fairly so described. We are, however, of the opinion that too much has been made of such cases. It cannot be and it is not true that a vice even after long indulgence is always master and cannot be withstood. It is equally certain that apparently confirmed inebriates and morphine

takers have been enabled to release themselves and have remained in a state of freedom. The force of habit, whether innocent or hurtful, is usually very great, but this by no means implies that it must necessarily, even after long duration, annihilate the other controlling forces of will. To what extent it may have done so remains in many cases an unsolved problem, and in this very uncertainty lies the germ of hope. Unless we recognize this potent fact all prospect of reform, all reason for the efforts of temperance even, may be abandoned. No amount of therapeutics will make a bad man good, or a drunkard abstemious, unless he is allowed credit for such will power as he has and is assisted or obliged to use it for his moral reclamation. While, therefore, we do not deny the existence of the states known as dipsomania or morphinomania, we deprecate as pessimistic and subversive of rational treatment the too general tendency to apply these and like terms to all aggravated forms of self-indulgence."

Medical Attachés to German Embassies.—Some Berlin periodicals, in discussing the possibility of an outbreak of plague in Europe, propose that medical attachés should be appointed to the German embassies abroad, and should be assigned the duty of studying the hygienic conditions of the countries where they happen to be stationed, and of promptly informing the German government of the occurrence of cases of infectious disease. The arrangements should be settled by international agreement, and in this way international regulations for the notification and prevention of epidemic diseases might be put on a more satisfactory footing than at present. Precedents already exist for embassies having attachés charged with other than diplomatic functions because agricultural experts, architects, and engineers have for many years held appointments in connection with the German embassies in order that they may inform the government of anything remarkable happening in their respective branches in foreign countries. The position of the medical attaché would be analogous to that of the other technical attachés.—Berlin correspondent of *The Lancet.*

The Pneumonia of the Aged.—Professor Lemoine (*Le Nord Médical*, August 15, 1900, p. 181) discusses the treatment of pneumonia in the aged, so far as it differs from pneumonia in the adult. The differential characteristics of the affection are briefly as follows: As in the adult the onset may be marked by shivering; dyspnœa may occur, but as a rule it is not intense; the pulse does not exceed 90 to 100; expectoration, generally slight in amount, is ordinarily composed of greenish masses; the cough is not very frequent; the temperature follows a similar curve to that in the adult, but is a degree or more lower. The summit of the lung is more often affected than the base. Stethoscopic examination may give the same signs as in the adult, but in other cases absolutely nothing is heard and the diagnosis must depend upon the general symptoms. Between these two extremes we may get all varieties, but as a rule crepitation is absent and subcrepitant râles are most commonly heard. The indications on which treatment must be based are to diminish the afflux of blood, to calm the respiration, to sustain the heart and the general strength. In addition, the elimination of toxins must be aided and the expectoration must be facilitated. Hyperpyrexia is unlikely to occur. Acetate of ammonium and ether are among the most valuable stimulants. Alcohol is often most valuable as a general stimulant except in alcoholics. In these musk deserves to be more widely used. Strychnine and nux vomica are most valuable aids to expectoration because of their effect on the muscular tissue, which is deficient in power in these patients.—*Treatment.*

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended November 30, 1900:

		Cases.	Deaths.
Smallpox—United States.			
Alaska, Skaguay	November 24th	1	
Whitehorse	November 24th	1	
Kentucky, Lexington	November 17th to 24th	1	
Louisiana, New Orleans	November 17th to 24th	1	
Michigan, Detroit	November 17th to 24th	1	
Minnesota, Minneapolis	November 17th to 24th	3	
Missouri, St Joseph	October 1st to 31st	1	
Nebraska, Omaha	November 17th to 24th	3	
N. Hampshire, Manchester	November 17th to 24th	3	
New York, New York	November 17th to 24th	1	1
Ohio, Cleveland	November 17th to 24th	23	
Pennsylvania, Pittsburg	November 17th to 24th	3	
Steelton	November 17th to 24th	2	
Texas, Houston	November 17th to 24th	17	
Utah, Salt Lake City	November 17th to 24th	31	
Smallpox—Foreign.			
Belgium, Antwerp	November 3d	..	1
Bohemia, Prague	October 27th to November 3d	19	
British Columbia, Nanaima	November 23d	12	
Ecuador, Guayaquil	September 8th to 30th	..	33

WOUNDS OF THE HEART WITH A REPORT OF SEVENTEEN CASES OF HEART SUTURE.[1]

BY L. L. HILL, M.D.,

MONTGOMERY, ALA.

WHEN Sir John Erichsen visited Philadelphia in 1874, he said: "Surgery has attained its highest plane, and reached its limit of usefulness, and nothing in the way of improvement or advance need be looked for except in detail of technique." Were this remark of Erichsen applied to-day to the surgery of the heart, it would be as eminently correct as it was woefully wrong then as to surgery in general.

Strange that the credit of the wondrous achievement of completely revolutionizing surgical treatment by the introduction of the methods of asepsis and antisepsis—the chart and compass of all surgical advancement—is due to Erichsen's former house surgeon, Joseph Lister, whose name is imperishably embalmed in the memory of man wherever surgery is taught as a science, and practised as an art.

Wounds of the heart may be either non-penetrating or penetrating—injuring the cardiac wall or opening a cavity. The chief dangers from the former are shock and injury to a coronary artery. Ninety per cent. are penetrating. The right ventricle is most frequently injured, and the left auricle is least so. Auricular wounds are more fatal than ventricular, and injuries to the apex are less dangerous than either. A needle puncture will rarely cause hemorrhage from a ventricle, but excessive bleeding is liable to follow a like injury to an auricle. A wound inflicted during diastole is less dangerous than a similar injury during systole, perpendicular wounds are more fatal than diagonal, and those of the right heart bleed more profusely than those of the left. The presence of the foreign body in the heart, the size of the wound, the number of the wounds, the connecting of cavities, the attending syncope, the involvement of Kronecker's co-ordination centre, are important factors in determining the outcome. Pericarditis, myocarditis, endocarditis, and empyema are frequent secondary complications.

When the wound heals there is a possibility of cicatricial stretching and subsequent rupture as in a case reported by Izzo of a man stabbed in the left ventricle, who was conveyed to the hospital from which he was discharged cured on the twenty-eighth day; a few hours afterward, while lifting a heavy body, he fell and quickly died. At the autopsy the cicatrix of the left ventricle was found ruptured. Blows upon the chest are more liable to cause rupture of the heart after a full meal, as the distended stomach pushes the heart upward and forward, and causes a large area of the organ to be in contact with the thoracic wall and receive the impact. Newton and Gamgee have collected forty-five cases in which traumatisms caused rupture of the heart without opening the pericardium. All were fatal. Only one of Gamgee's cases survived the injury fourteen hours. The fatality is easily understood, for there being no exit, as soon as the accumulation of blood exceeds the limit of pericardial distensibility, the cardiac movements are mechanically stopped. The surgeon not only would be justified, but it is his bounden duty to operate upon every one of these cases, for it is more important, if possible, to rescue a drowning heart than to relieve a strangulated gut. It is possible for a foreign body, as a gun missile, to remain quiescent for years in the myocardium, as in the case of a British officer, reported by Stevenson, who carried a bullet encapsuled for eleven years, or the still more remarkable case of Beers (Cincinnati *Lancet Clinic*, 1898), of an American soldier who survived the lodgment of a bullet in the wall of the left ventricle for thirty-seven years. I can better illustrate the symptoms of these injuries by a brief report of two cases that have come under my observation.

CASE I.—M. J——, female, eight years of age, was brought to my home by her father on the night of January 5, 1897. She had carried in her shirt waist a needle two and a half inches in length, which she had driven into her heart by accidentally falling against a tree.

Her countenance was anxious, pulse rapid and weak, and respiration somewhat labored. She had slight pain about her heart. Upon inspection I found that the foreign body had entered the fifth intercostal space on the left side, and with the pulsation of the heart the head of the needle could be seen to move under the skin—a symptom centuries ago enshrined in the magnificence of indestructible verse:

> "He fell, the spear point quivering in his heart
> Which, with convulsive throbbing, shook the shaft."

The case being one of unusual interest to me, I summoned my friend Dr. R. F. Michel, and my brother Dr. R. S. Hill, and proceeded to operate by injecting ten drops of a four-per-cent. solution of cocaine into the skin. I made an incision an inch in length down to the needle, and extracted it with a pair of dressing forceps. The wound was immediately closed, and the child sent to a relative's house, with instructions to the parent that they detain her in bed, and that she be kept quiet for ten days. She had no subsequent trouble.

CASE II.—Through the courtesy of Dr. J. M. Anderson I had the opportunity of examining Robert F——, colored, twenty-eight years of age, who had received a stab wound in the fourth intercostal space a little to the right of the left nipple. Seen shortly after the injury there was complete relaxation of the extremities, and the pulse was hardly perceptible. The countenance depicted a suffering and distress that would seem to welcome death with the wintry sterility of the grave as a kind and sympathizing friend. Auscultation revealed the heart sounds very indistinct, and percussion elicited increased dulness. It was evident that the pericardium was rapidly filling with blood, and that the heart's action would soon be overcome by compression. The external hemorrhage was slight. The blood was evacuated by enlarging the opening in the pericardium, and the patient's condition at once

[1] Read before the Jefferson County Medical and Surgical Society at Birmingham, Ala., on November 12, 1900.

improved, and he ultimately recovered, though subsequently traumatic pericarditis supervened.

Treatment: I presume no one will question the propriety of operative interference, as experience demonstrates that a little in excess of forty-one per cent. recovered that had been operated upon, as against ten per cent. of recoveries in cases in which no operation had been performed.

For temporary hæmostasis some operators have recommended Péan's forceps and various modifications of it, but they all more or less lacerate the myocardium and can never replace digital pressure. All are agreed that interrupted sutures are preferable in closing a wound of the myocardium; they should be close together and not involve the endocardium. Giordano from his experiments upon rabbits concludes that auricular wounds might be closed advantageously with Lembert's sutures. Silk is preferable to any other material. The needle should be the same as that used in suturing the intestines. The sutures should be passed and tied during diastole. The first suture may be used to steady the heart and facilitate the passage of the others. In sewing the pericardium either interrupted or continuous sutures may be used.

It hardly seems necessary to accentuate the fact of the necessity of perfect cleanliness in these operations whenever the urgency of the case does not require instant intervention as in the patients of Longo and Ninni.

The question of administering an anæsthetic is a mooted one. Ollier says general anæsthesia should not be thought of. Parrozzani operated upon his two cases without an anæsthetic, and observed only slight movement when he cut the skin and in passing the sutures in the myocardium. Giordano made the same observation in his case, but thinks Ollier's statement is too sweeping, as if the pulse is strong and the general condition good chloroform may be administered. Struggling from an anæsthetic is liable to produce detachment of a clot and renew the hemorrhage, as occurred in Parlavecchio's case. I have been able through the valuable assistance received from the writings of Professor Giordano to give here the history of the seventeen recorded cases of heart suture.

Case I.—Farina, of Rome, in 1896, sutured a wound of the right ventricle 6 mm. in length. The dagger entered just above the upper margin of the sixth rib, near the sternum, on the left side. Operation was performed by making an incision four inches in length along the superior border of the sixth rib, which was divided at the sternum. Divarication was made of the fifth and seventh rib. The opening in the pericardium was enlarged, the wound in the right ventricle closed with three silk stitches, and the pericardium sutured. Stimulating injections were given and autotransfusion was practised. The pulse at times became very rapid. The patient died on the sixth day of broncho-pneumonia. At the autopsy the wound in the ventricle was found cicatrized.

Case II.—Cappelen, in 1896, operated upon a man twenty-four years of age, who had been stabbed one hour before entering the hospital. The knife had entered the fourth left intercostal space in the mid-axillary line. The wound was 1 cm. in length, and there was no external bleeding. The left half of the thorax was immovable from compression of the lung due to an accumulation of blood in the pleural cavity. The pulse was imperceptible, and the heart sounds were heard with difficulty. The third and fourth ribs were resected, and the blood in the pleural cavity was evacuated, which permitted the lung to expand. The pericardium was distended with blood, and when emptied a wound of the left ventricle, four-fifths of an inch in length, was observed. One of the large branches of a coronary vessel was cut. The artery was tied, and the wound in the ventricle sutured. The patient was very weak but improved after an injection of a saline solution. He died several days afterward of pericarditis.

Case III.—Rehn, of Frankfort-on-the-Main, operated upon a young man who had been stabbed with a dagger in the fourth left intercostal space in proximity to the sternum. He was found unconscious upon the street and carried to the hospital. The following day his condition was more favorable in the morning, but toward evening there were signs of oppression, and extreme dulness extended to the top of the left lung. An incision was made along the fifth rib, which was resected. The pericardium was greatly distended, and upon being emptied a wound of the right ventricle was observed, from which blood came at every diastole. It was sutured with three silk stitches. They were introduced and tied during diastole The pleura and pericardium were drained. The patient had suppuration of the pleura but eventually recovered. This is the first successful case of heart suture in man recorded. The patient was presented to the Congress of German Surgeons in Berlin in 1897.

Case IV.—Parrozzani, in 1897, operated upon a young man who had been cut three times. Two of the cuts were of no importance. He followed his assailant thirty steps and fell. Five hours after the injury he was carried to the hospital, where it was found that the dagger had entered the seventh left intercostal space in the mid-axillary line. His general condition was extremely grave—"heart beats and pulse almost imperceptible, and respiration rapid and superficial." Immediate intervention without an anæsthetic was decided upon. An incision through the soft parts one and one-fourth inches from the margin of the sternum in the fourth intercostal space was carried for a distance of five and one-half inches, then it descended vertically in the mid-axillary line as far as the superior margin of the ninth rib. The fifth, sixth, seventh, and eighth ribs were cut through in the mid-axillary line with the pleura. The musculo-osseous flap or door was raised, with the cartilages of the ribs acting as the hinges. The pleural cavity was filled with blood and an opening one inch in length was found in the pericardium which was subsequently enlarged to two and a half inches. There was very little blood in the pericardium, because the injury was in the most dependent part and the blood readily escaped into the pleural cavity. A wound in the apex was observed three-fourths of an inch in length, through which the little finger was passed into the left ventricle. This served the double purpose of checking the hemorrhage and steadying the organ for the introduction of the sutures. Four deep silk stitches were used, not touching the endocardium. Passing the needle caused violent throbbing of the heart. The pleura and pericardium were thoroughly cleansed, and the flap was sutured in position. Stimulating hypodermic injections were used, and hypodermoclysis and autotransfusion practised. The operation lasted one hour and a quarter. Recovery resulted. For the full report of this case I am indebted to Dr. G. Sanderson Brock, to whom details were given by Dr. Parrozzani.

Case V.—Parrozzani operated upon a woman who had been stabbed in the third left intercostal space. Half an hour afterward she was conveyed to the hospital. Her condition was exceedingly unfavorable. She was operated upon immediately without an anæsthetic, the operation being very similar to the other, excepting that the fourth, fifth, and sixth ribs were cut through. The pericardium was found filled with blood, and upon its evacuation an opening in the anterior wall of the left ventricle about three-fifths of an inch in length was observed. This was closed with two stitches. Hypodermoclysis and stimulating

injections were employed. The patient died on the second day. The autopsy revealed that the interventricular septum had been cut. There was profound anæmia.

Case VI.—Fummi reported in 1898 that a patient had been stabbed under the left nipple. Several hours afterward an operation was performed, and the pericardium was found dilated with blood. The wound was in the apex but did not open a cavity. It was closed with one stitch. Hypodermoclysis was employed. The patient had empyema but recovered.

Case VII.—Ninni reported in 1898 a patient stabbed in the fifth left intercostal space. The man was quickly carried to the hospital and subjected to an operation without an anæsthetic. An incision was made outward from the sternum along the superior border of the sixth rib. A parallel incision along the inferior margin of the third rib was made. They were united by a vertical incision. The fourth and fifth ribs were cut through, and the shutter was turned back toward the sternum. The pericardium was found enormously distended with blood. There was an opening into the left ventricle through which the surgeon introduced his right index finger, which acted as a stopper, but upon substituting his left so as to sew up the wound a violent hemorrhage followed. Three interrupted stitches closed the cardiac wound, and a continuous suture had shut the pericardium, when the operation was discontinued on account of the patient's death.

Case VIII.—Parlavecchio, in 1898, operated upon a patient who had been stabbed in the fifth left intercostal space. The wounded man went to the hospital. After five hours blood was observed in the pleural cavity. The pulse became very weak and intermittent, and the heart sounds were heard with difficulty. Intervention after eight hours was resorted to under chloroform. The fifth rib was resected. The finger was introduced, and the wound in the pericardium was grasped and enlarged. There was a wound of the apex about an inch and a half in length, penetrating obliquely the left ventricle. It was closed with four interrupted sutures. After thorough cleansing the pericardium and external wounds were closed. The duration of the operation was forty minutes. Recovery took place.

Case IX.—Giordano, in 1898, reported the case of a man who had been stabbed through the second left intercostal space. When he reached the hospital a half-hour after the injury he was thought to be dead. Immediate operation was done without an anæsthetic and without cleansing of the field of the operation. The introduction of the index finger showed that the wound ranged downward and inward. An incision was made extending from the wound to the margin of the sternum; a second incision from the sternal end of the first descended to the superior margin of the fifth rib. The third and fourth ribs were cut through, and an immense quantity of blood was evacuated. When the pericardium was opened a wound in the left auricle, four-fifths of an inch in length, transverse to the axis of the organ, was observed. Bleeding was very free. Four silk stitches were introduced, which was done in less than fifteen minutes. The third rib was placed in position, but a portion of the fourth was resected for free drainage of the pleural cavity. Stimulating injections were given and autotransfusion was employed. Empyema commenced a few days later and the ninth rib was resected. Death occurred on the nineteenth day. The autopsy revealed many abscesses in the right lung. This is the first recorded case of suture of an auricle.

Case X.—Nicolai, in 1899, operated upon a man who had been stabbed in the fourth left intercostal space midway between the margin of the sternum and the nipple. The point of the dagger ranged upward. He was operated upon under an anæsthetic one and one-half hours after the injury. The fourth and fifth ribs were divided, and a wound in the right ventricle was found and sutured. The patient's condition seemed favorable, but death occurred suddenly twelve hours after the operation. At the autopsy the pericardium was found empty, and the sutures were in position.

Case XI.—Tuzzi saw a man who had been stabbed in the fourth left intercostal space. Intervention was done without an anæsthetic. The fourth and fifth ribs were divided as in the previous case. There were two wounds of the myocardium—a penetrating and a non-penetrating. There was a coagulum between the lips of the former. The cardiac wound was sutured, and the pleura drained. Hypodermoclysis was performed. The patient died on the twenty-second day of empyema. At the autopsy it was discovered that the patient had sero-fibrinous pericarditis, and that the wound of the heart had healed.

Case XII.—Longo reported a case in which the knife entered at the fifth left intercostal space two-fifths of an inch internal to the nipple. The patient's general condition was so unfavorable that the operation was performed at once without an anæsthetic. A vertical incision was made from the lower border of the third rib to the superior border of the sixth rib, two-fifths of an inch from the sternal margin. A second incision parallel to the preceding was made through the nipple, and a third united their lower ends. The fourth and fifth ribs were divided. There was found an opening, one and one-fifth inches in length, in the pericardium, which was enlarged, and a wound of the left ventricle was discovered and closed with three interrupted silk stitches. The pericardium was closed with continuous sutures. The patient was transfused with a saline solution, but died in fifteen minutes.

Case XIII.—Ramoni reported that his patient was stabbed at the third cartilage four-fifths of an inch to the left of the sternum. Without an anæsthetic an incision was made about four inches in length along the third rib from the sternum. Two vertical incisions descended from each end of it, and the third, fourth, and fifth ribs were cut through. The pericardium was emptied of blood, and two wounds near the base of the right ventricle were observed. A suture was passed during diastole which provoked a strong systole, causing a laceration of the myocardium and abundant hemorrhage. The finger was introduced and the opening closed with four interrupted sutures, which did not pass through the endocardium. Stimulating injections, autotransfusion, and hypodermoclysis were at this time resorted to. The second wound was closed with two stitches. The pleura was drained. The operation lasted three-fourths of an hour. Recovery took place.

Case XIV.—Marion reported, in 1899, a patient who had been shot through the breast. The fourth, fifth, and sixth ribs and a part of the sterum were cut. The wound of the myocardium was sutured. The autopsy showed that the missile had passed entirely through the body.

Case XV.—Rosa reported, in 1899, that a man upon whom he operated was stabbed in the fifth intercostal space. Operation was performed without an anæsthetic. An incision four inches in length was made along the fifth rib. It was resected, and a severe hemorrhage from a wound of the lung was stopped with a stitch. The sixth, seventh, and eighth ribs were cut in the anterior axillary line. The pericardium was emptied of blood, and a wound of the left ventricle, near the base, three-fifths of an inch in length was observed, but the operator could not say whether it

penetrated the cavity. It was closed with one stitch, and the pericardium and pleura were drained. Recovery resulted.

Case XVI.—Pagenstecher reported his case in 1899. The dagger entered the fourth left intercostal space beneath the nipple. The patient came under observation a half-hour after the injury, and it was discovered that there was no external bleeding. The pulse was imperceptible, and respiration had almost stopped. The corneal reflex was abolished. Dulness extended over almost the whole left side of the chest. The patient was operated upon sixteen hours after the injury by an incision along the fifth rib, which was resected about two and one-half inches. The opening in the pericardium was enlarged two inches, and a wound was observed of the left ventricle about one and one-third inches from the apex and one and two-fifths of an inch long, from which ran a stream of blood. Three deep celluloid sutures and one superficial one were used. The pleura was cleansed and the pericardium sutured. The threads of the knots in the myocardium were left long, so as to come through the external wound. Pulling the threads on the ninth day caused two to come away, and the other two came ten days later. Recovery took place.

Case XVII.—Maselli reported, in 1900, the case of a man who had been stabbed below and internal to the left nipple. He revived a little after injections of ether and caffeine. He was operated upon one and one-half hours after the injury without an anæsthetic. A transverse incision was made from the margin of the sternum to a point beyond the nipple. About two and a half inches of the sixth rib, which was cut by the weapon, was resected. The lips of the wound of the pericardium were caught with Péan's forceps and drawn toward the external opening. The finger was introduced, and a wound of the left ventricular wall discovered near the apex, which was closed with two sutures. The pericardium was cleansed and continuous sutures were used. The pleura was drained with gauze. Stimulating injections, hypodermoclysis, and autotransfusion were employed. The operation lasted more than an hour. At first the patient improved, but twelve hours later symptoms of collapse appeared, which did not yield to a repetition of stimulating injections and hypodermoclysis. The autopsy showed that one of the stitches in the myocardium had become untied, but the edges were in apposition, and the pericardium was empty.

John Bell, who was far in advance of his time, taught and practised pericardiotomy, removing foreign bodies and washing out the sac. Dr. John B. Roberts, of Philadelphia, in 1881, suggested heart suture, and Dr. Del Vecchio, of Naples, in 1894, demonstrated its feasibility before the Eleventh International Medical Congress in Rome, by his experiments on dogs. Two years later the human heart was sutured by Farrina and Cappelen. It is surprising to find the statistics collected by Fischer, of Breslau, in 1868, quoted by leading text-books on surgery as late as 1900 as authoritative in computing the prognosis in this class of injuries. The successful suturing of the heart by Rehns, Parrozzani, Parlavechio, and others has revolutionized the treatment and changed the probable outcome. Fischer's statistics, though a monument to his untiring zeal and energy, are now like an antiquated sign-board on a discarded highway; but

> "Faith, fanatic faith, once wedded fast
> To some dear falsehood, hugs it to the last."

Anti-Cigarette Laws.—The Vermont legislature before its recent adjournment passed a bill prohibiting the sale of cigarettes in the State. The bill passed both houses of the legislature and has been signed by the governor.

INTERNAL HEMORRHAGE, THE RESULT OF TRAUMATIC RUPTURE OF ADHESIONS DUE TO ACUTE APPENDICITIS, WITH THE REPORT OF A CASE.

By LOUIS J. LADINSKI, M.D.,

ADJUNCT PROFESSOR OF GYNÆCOLOGY, NEW YORK POLYCLINIC; VISITING SURGEON, GOUVERNEUR AND BETH ISRAEL HOSPITALS

The patient is a boy eleven and one-half years old, whom I saw in consultation with Dr. M. Girsdansky. Family and previous history is negative; there is no personal or family history of hæmophilia.

On Wednesday, August 1, 1900, he complained of slight cramps in the abdomen; at no time, however, was the pain severe enough to prevent him from playing and jumping about. On the same day, at about 7 P.M., while sliding down the balustrade, he lost his hold and landed with considerable force upon the floor. He was picked up and carried to his room, complaining of severe pains in the abdomen and suffering from nausea and vomiting. On the evening of

Fig. 1.—Site of Rupture Shown at Junction of Concave and Perpendicular Portions of Specimen.

August 2d, Dr. Girsdansky was called in to treat the patient. He found him lying in bed with legs drawn up and moaning constantly; his face pale, anxious, and drawn; breathing was labored, pulse 120, small and hard, and occasionally irregular, and the temperature was 101° F. On examination he found the abdomen to be painful and tender; tenderness was especially marked in the lower abdomen. The boy had urinated regularly and normally, and had had a movement of the bowels. He ordered small doses of calomel and ice applications, and decided to wait for surgical interference till the next morning, when, on finding the patient much worse, he invited me to see the case with him.

I saw the boy at twelve o'clock on the 3d of August, about forty hours after the fall, and found him in a condition of extreme collapse; his pulse ranged between 130 and 140, small and irregular; his temperature was 104°, and the breathing rapid and shallow. There was general cyanosis; the face was anxious and drawn, and the eyes were deeply sunken. The abdomen was very much distended, extremely tender and sensitive, and was tympanitic above and boggy below. There was distinct evidence of fluid in the peritoneal cavity. The pain and the tenderness were slightly

more marked in the region of the appendix. In short, there was every sign and symptom of a general peritonitis.

The differential diagnosis was between hemorrhage from some internal organ, rupture of the bladder, rupture of the intestine, and general peritonitis due to a rupture of an unrecognized appendicitis. Rupture of the bladder was dismissed from consideration for the reason that the urination was absolutely normal. Rupture of the intestine was excluded because the bowels had moved, and there was no evidence of gas in the peritoneal cavity. The collapse, cyanosis, and the high temperature pointed to a septic condition which could not be accounted for by a simple internal hemorrhage. Considering the fact that the boy had had an attack of abdominal pain previous to the fall, and viewing all the signs and symptoms in the light of past experience, a diagnosis of general peritonitis, due to ruptured appendicitis, was made.

Though a fatal prognosis was given, the parents accepted the slight chance an operation offered. The boy was transferred by ambulance to my service at Gouverneur Hospital, and was at once placed upon the table and prepared for operation. A median incision was made, and when the peritoneal cavity was opened, it was found to be filled with blood. As much as possible of the blood was sponged out and mopped up. The appendix was sought for and was isolated from the surrounding parts by means of pads; and on carefully exposure and drying of this region it was found to be the site of the hemorrhage. The appendix, which was unusually long, was doubled up like the letter U, being held in that position by the adherent meso-appendix, and lay in front of and to the inner surface of the cæcum, to which it was attached by recent adhesions. The entire appendical region was injected and congested. At the bend of the meso-appendix there was a rent to the extent of about a half-inch, in which several small spurting vessels were distinctly made out. The meso-appendix was ligated; the appendix was separated from the adhesions and removed; the blood and clots were wiped away, and the peritoneal cavity was washed with saline solution and the wound closed. The following day the temperature dropped to normal, and the boy made an uneventful recovery, being discharged from the hospital thirteen days after the operation.

The fall undoubtedly caused the tear in the meso-appendix, which was the source of the hemorrhage in the peritoneal cavity, and the sepsis was due to the appendicitis. The case is undoubtedly unique. As far as I can learn from the literature up to date, there has never been reported a similar complication in acute appendicitis. Dr. Edebohls, in his excellent résumé of the literature of appendicitis, cites cases of hemorrhage complicating appendicitis as a result of ulcerative processes of the small intestines;[1] of the sigmoid;[2] of the right external iliac artery;[3] of the right iliac vein;[4] and in a conversation with him Dr. Edebohls informed me that he had a record of a case of fatal hemorrhage due to the slipping of a ligature of the artery of the meso-appendix, but he corroborates the statement that there is no previous record of a traumatic internal hemorrhage from vessels of the meso-appendix. The case is of further interest because of its very close similarity to general peritonitis, the result of perforative appendicitis.

INSANITY, ITS CAUSES: IS THERE IN WOMAN A CORRELATION OF THE SEXUAL FUNCTION WITH INSANITY AND CRIME?

By MARY DIXON JONES, M.D., F.R.M.S.,
NEW YORK.

That the brain is the organ of the mind must be recognized as a fundamental fact, as an axiom in mental science and in the pathology of "mental diseases."

The brain, with its wonderfully complex structure, its many varied and complicated parts, is the organ or instrument by which the intellectual and moral powers make their manifestations; and any indication of mental disease or inability to carry on any of the mental processes must come from some abnormal condition, disease, or structural lesion of the brain. If the mental faculties make abnormal presentations, or if insanity in any form occurs, it is only because some tissue or structure of the brain is diseased or in some temporary or chronic pathological condition. It is not that the mind—the mentality, the thinking part of our being—is diseased. And whenever there is any morbid or diseased condition of the brain it will be shown in the mental operations. They will be more or less disturbed or abnormal. When the brain is diseased, as from a musical instrument out of repair there are given forth uncertain sounds. One part may be diseased and another portion sound, so that there may be a union of abnormal and normal manifestations; but we will ever find the causes of insanity to be in the varying conditions of the brain substance. This is the only true theory, any other leads into mazes of doubt and mystery, and to an infinite number of vague speculations.

The brain is the great masterful organ of the whole body, surpassingly wonderful in every part of its anatomical structure, and far beyond our comprehension in its mode of acting, the manner of its manifestations, and in its methods of giving expression to thought, feeling, and the emotions.

We cannot begin to comprehend the wonders and powers of the human brain, nor can we understand all the high mysteries of what is the mind, or what is the spiritual part of man. "God breathed into him the breath of life, and man became a living soul." So the living soul, or mind, is of God. It is immortal, eternal, everlasting. It does not get sick or die, and from it does not come mental disease.

That the brain is the instrument or organ of the mind we have the testimony of many eminent writers. Sir William C. Ellis, superintendent of the Middlesex Lunatic Asylum in England, declared:[1] "Insanity is a disease of the brain." J. M. Cox in 1805 said:[2] "I am inclined to believe that in every case of insanity, be the remote causes what they may, the proximate causes reside in the brain." Dr. John S. Gray, who has done excellent work in this department, at one time editor of *The Journal of Insanity*, and professor of psychological medicine in Bellevue College, 1868, said:[3] "Insanity is now generally recognized as a disease of the brain. A necessary antecedent to madness is a disordered physical state of the brain, that it never occurs in a person of sound brain." C. B. Coventry, professor of obstetrics and medical jurisprudence, Geneva College, wrote:[4] "Insanity is only a symptom of derangement of some portion of the brain. That the brain is the instrument or medium of all mental and moral manifestations, is a fact so clearly established and susceptible of demonstration."

[3] Journal of Insanity, 1872, xxix., p. 261
[4] Trans. of the Med. Soc., State of New York, vol. v., 1841–43.

Henry Maudsley says:[1] "Insanity is disorder of the brain producing disorder of the mind." Dr. Folsom, lecturer on hygiene and mental disease in Harvard University, wrote:[2] "No one will pretend to deny that the brain is the organ of the mind, and that anomalous action of the mind depends directly upon abnormal conditions of the brain, idiopathic, functional, or reflex." Tuke says:[3] "Insanity consists of morbid conditions of the brain," and Morel declares[4] that "all these extraordinary phenomena have their seat in the brain, and we will find when we prove them, that it is the brain that is not sound (c'est que le cerveau n'est pas sain)."

Going far back to the close students and clear thinkers of ancient times, Hippocrates more than two thousand years ago declared:[5] "It is by the brain that we think, comprehend, see, understand, that we know the evil and the good, the agreeable and the disagreeable. . . . It is, too, by that we are fools, by that we are delirious, and by that the fears or terrors besiege us by night and by day." Lord Bacon, with his clear intuition, said: "If ever the true nature of insanity was discovered it would be found to exist in corporeal changes, or the effects of external agents acting on the gross machines, not on the immaterial principle."

F. Winslow,[6] in his book on "Diseases of the Brain," tells us "Defour attempts to prove that the brain has directly no connection with insanity, that alienation of the mind is consequent upon some affection of the nervous ganglia of the abdomen, and that Fodéré imputes insanity to an alteration of the vital principle, and that Pinel is of opinion that insanity frequently arises from visceral complications."

Bancroft says: "I fully admit that a large proportion of cases of insanity even in both sexes are of reflex origin, and not the result primarily of cerebral disease." Storer[7] tells us that Workman, of Toronto, argued for the extracerebral causation of insanity that, unless in confirmed low dementia and idiocy, insanity has no necessary connection with diseased brain properly so-called. Storer admits that "the brain is the seat of insanity, but not always of its cause; that we are compelled at times to seek the ultimate cause of insanity outside of the brain," adding: "Of the various forms of insanity occurring in females, the majority of them are owing to functional or organic diseases of the uterus and its appendages."

So an infinite number of causes of insanity are given by different writers. Scarcely an organ or function of the body, or any human act or passion but has been presented as a cause.

Forbes Winslow makes the inquiry: "Whether there is any specific and clearly definable characteristic organic alterations in the encephalic mass invariably present in insanity and that can be considered to stand in relation to cause and effect." He adds: "I have often been much surprised when examining the heads of patients who have died from the effects of acute insanity, by the remarkable absence, or even an approximation to an adequate physical cause of the fatal disease."

There is reason to believe that in all cases of insanity there will be found in the brain some corresponding pathological condition. In many organs of the body we have often observed that even profound pathological changes cannot always be recognized by the naked eye.[1] I believe in all cases of acute or chronic insanity there are structural changes in the brain. John S. Gray says:[2] "We are every day discovering structural degeneration of brain tissues which throws more and more light on causation."

Storer asserts that insanity may exist without structural changes in the brain, quoting the following authorities to sustain his views: Bell, of MacLean Asylum, "Autopsies of the insane generally present no material lesion of the brain"; Worthington, "Insanity is unattended with any organic cerebral change, the disease is very commonly consecutive to disorders of the general system;" Bucknell, "A large number of brains of the insane we have diligently investigated with a first-rate microscope. The results appear to us to have afforded no distinction between the sane and the insane brain."

In opposition to these views, Armstrong declares that in regard to the anatomical pathology of insanity he has never seen the body of a patient who died mad in which there was not disease of the brain; that he has never seen an autopsy without some one unequivocal appearance of organic change presenting itself to the careful and patient examiner. Portal writes as follows: "Morbid alterations in the brain and spinal marrow have been so constantly observed, that I should greatly prefer to doubt the sufficiency of my own senses than to believe that mental disease could exist without any physical disease of this viscus." Dr. Brigham, one time editor of *The Journal of Insanity*, says: "On examining the heads of those who die insane, some disease of the brain or appendages is generally found."

Probably, if these diseased portions of the brain were prepared by the best processes for microscopical investigation, we should find a more wonderful record than we have yet conceived of. Dr. Davison, of the Lancaster County Lunatic Asylum, says he scarcely ever met with a single instance where traces of disease either of the brain or membrane were not evident. Dr. Clutterbach, of Great Britain, says: "I think we are warranted in attributing every disorder of the mental functions to a diseased condition of the brain as its immediate cause, of which the derangement of the intellect is but a sign or symptom." Another writer adds: "The reason why it is not detected is owing to our defective means of examination." Ellis in his excellent work wrote:[3] "We know quite as little of the anatomy of the brain as of any other part of the human body." E. C. Mann declares that "the pathology of insanity is as yet in its infancy." Still we should endeavor to look into it, for, as Maudsley says:[4] "We have not to deal with disease of a metaphysical character which the methods of inductive inquiry cannot reach, nor the resources of the medical art touch, but with disease of the nervous system, disclosing itself by physical and mental symptoms."

The question is asked, Is there in woman a "correlation of sexual function with insanity and crime?" Would not this prove some defect in the formation of one-half of the human race? As little could I believe that menstruation, when normal, originates morbid impulses. Can any normal function give rise to abnormal impulses? Is it likely that in a young girl, in this her first function of womanhood, are originated

morbid impulses? Many a young woman I have seen suffering almost untold agony during this period, yet there were no abnormal impulses, nor was the young girl prompted to any crime, nor did she manifest any criminal intent. She was an angel in goodness, purity, and innocence, and a martyr in her sufferings.

Menstruation naturally should be a normal function, and should not be accompanied by any suffering or pain.[1] Only past violations of the laws of health make these conditions of suffering. I know women who during all the long years of their lives had never one painful menstruation. But even abnormalities of the menstrual function and the sufferings thereof have no correlation with, nor do they point to or lead to crime. The criminal intents are in the individual's mind and heart. Nothing could be farther from a true presentation of the subject than that the process of menstruation, or abnormal conditions thereof, affect a woman by originating morbid impulses and criminal intents.

Just as impossible is it to believe that that most complex function, ovulation—as yet unexplained—when normal is, in any of its processes, a source of irritation, or of the least disturbance to the mental organization; nor does this high function originate morbid impulses. Ovulation is a normal process, controlled by fixed laws, and when normal makes no mental disturbance, nor has it any connection with or tendency to produce insanity. I believe the performance of any and every function, when normal, contributes to and helps perfect the general health, mental and physical. The whole system, every part and every function, in a state of health is in such harmony that it is almost the music of the spheres, and even more beautiful.

It is true and is recognized by many eminent physicians that a disease of the genital organs in woman may be a source of great irritation and disturbance to her whole system, and may cause such exhaustion and prostration as to produce extreme nervousness, and, in some cases, more or less abnormal manifestations, and even mania and insanity. But these mental abnormalities can take place only in those who have some neurosis, brain lesion, or disease of the brain of some kind, or an inherited tendency thereto. In over one hundred laparotomies performed in the Woman's Hospital of Brooklyn for some of the worst and most varied forms of pelvic disease, there were four cases of abnormal mental conditions.

Case I.—Ovaries and tubes showed most serious conditions of disease. The cervix and perineum were lacerated, the torn edges of each covered by hard cicatricial tissue. All these conditions were not only sources of suffering and ill health, but apparently of abnormal irritations to her nervous system. Her mental conditions were so disturbed that her friends thought she was becoming insane. The patient told me that she felt as if she must kill some one, that many times she felt like killing her own children.

This woman, no doubt, had some inherited tendency to insanity. There was some lesion of the brain, and the diseased condition of the pelvic organs proved to be a source of increased irritation to this already sensitive and diseased brain. These pelvic conditions were also destroying her physical health, and rendering her system less able to overcome and prevent the devastating results of the brain lesion. Such a diseased condition of the genital organs would in the most sane woman have been a source of great distress and disturbance to her general health. This mentally affected woman was less able to bear it; it was such an irritation that it had a tendency to increase or excite an abnormal mental condition. Indeed, this diseased condition of the genital apparatus may have been at first the exciting cause to an already diseased brain to awaken the abnormal manifestations; but it was only because of a pre-existing brain lesion, or the brain was by some defect, disease, or inherited tendency predisposed to insanity.[1] I have repeatedly found equally and profoundly diseased conditions of the genital organization, in women suffering infinitely more, and not the least indication of, or tendency to, mental aberration.

We often find some of the worst forms of disease of the genital organs, continued suffering for years, accompanied by the greatest prostration in those who are mentally sound, or who have no structural lesion of the brain or inherited tendency thereto, and there will be no indications of insanity. Manifestly these diseased organs in this partially insane woman were not only destroying her health, taking her strength, endangering her life, but were an irritation to the whole nervous system, and increasing her tendency to insanity. The removal of such hopelessly diseased structures and repair of the surgical injuries were certainly demanded in her case, and would have been a blessing to any woman who had similar conditions, whether sane or insane. The diseased tubes and ovaries, so bound in adhesions, were removed; as was the cicatricial tissue from the cervix and perineum, and the gaping wounds were sewed up. All indications of insanity disappeared in her case; she was under observation some two or three years, apparently in good mental and physical health. I saw the patient last in August, 1889. She was well and gave every indication of good health, both of body and of mind, and with proper care she may continue to grow stronger and stronger, mentally and physically. Yet, from adverse causes, there may be a return of the insanity.

Case II.—In 1887 I was requested by a physician in Bridgeport, Conn., to see a patient in the neighboring town of Ansonia. The patient was twenty-five years old, a teacher by profession, married six years; no children; weighed seventy-five pounds; temperature 101°. For five years she had been an invalid, unable to attend to her household duties. She was now confined to her bed, nervous, hysterical, and at times wildly insane, more than once threatening to take her own life. The patient was so weak, and so great were her paroxysms of pain, that a number of times her husband and mother thought she was dying.

She was carried in her husband's arms to the Woman's Hospital of Brooklyn, of which I then had charge, and while there she had hallucinations that could not be dispelled. The uterine appendages were found to be enlarged, sensitive, and low down behind a retroverted uterus. Every evacuation of the bowels caused extreme pain and almost a deathlike weakness. Menstruation was accompanied by suffering and a prostration so extreme that it did not seem possible for her feeble frame long to endure it. The patient had pyosalpinx on both sides and pelvic peritonitis. There seemed to be no other help than the removal of the diseased organs. After consultation it was decided to perform the operation, which was done in July, 1887. Dr. A. M. Jacobus was present. The patient made a good recovery, and at the end of the second week went up and down stairs without assistance, and rode out. At the end of the fourth week she

[1] I said in an article, Amer. Jour. of Obstet., February, 1888, p. 173: "The functions of ovulation and menstruation are physiological and their healthy performance certainly has a benign effect upon all the organs and functions of the body." In the Medical and Surgical Reporter, Philadelphia, May 27, 1893, I said: "A woman with a healthy genital organization goes through the function of menstruation as naturally, normally, and painlessly as the digestion of food by a vigorous stomach."

[1] I am glad to find a corroboration of my views by so excellent an authority as T. Claye Shaw ("St. Bartholomew's Hospital Report," vol. xxii., 1886, p. 105). "It seems the uterine affectioes do not cause insanity unless there is already a predisposition to it."

accompanied her husband home, and that day walked as much as a mile. Subsequently her general health and mental state still more improved, and she was soon able to attend to her household duties. The ovaries when examined microscopically were found to be not only in a state of intense oöphoritis, but there were large gyromatous formations; which latter, no doubt, were the cause of, or certainly intensified, the morbid conditions of the nervous system.

Such is about the report I felt justified in making of this case in 1890 and 1892.[1] I supposed the patient was well, that her abnormal mental conditions were relieved. I had then, and have still, no doubt that the large, solid, gyromatous formations impinged upon and compressed the nerves so as to cause severe reflex irritations. Yet all this suffering I do not believe would have caused insanity in this woman unless she already had some disease of the brain, or an inherited tendency thereto.

After the removal of the incurably diseased structures her health was so much better in every way that I thought she was cured both mentally and physically. But subsequently, amid the multiplied discouragements of her household—no pleasant lookout for a fine nature previously educated—there came again the depression and melancholy, and the slighter symptoms of insanity. I could imagine that if it had been possible for this woman to have the happiness of children, with that brightness and ever new delight she might have passed through life without another symptom of insanity. The removal of these diseased structures had, no doubt, greatly improved her health, and may have saved her from a more helpless madness; and, under more favorable circumstances, she might have been cured.

When these organs are incurably diseased I believe it is a blessing to any woman to have them removed. The removal not only saves much suffering, but in many instances saves her life, and tends to cure the mental malady.

Case III.—The third patient, Mrs. F——, with indications of insanity. Blood cyst in one ovary, endothelioma in the other; intense oöphoritis, waxy degeneration of the ovum. There was a great mental disturbance. The patient had suffered for some years, and was unable to attend to her household duties. After the operation she regained her health and improved in mental condition. She was under observation for several years, and at times I thought her mind was a little unbalanced. Yet I believed that after removing this source of irritation and suffering and increasingly bad health, there were, with proper care, many chances for the brain gradually to recover its wonted good health.

Case IV.—On May 30, 1888, a patient, Mary G——, was brought by her mother to me. She was an epileptic, had had repeated attacks of peritonitis, and now complained especially of great distress in the pelvis. One ovary was enlarged into a blood cyst, the size of an orange; there was pyosalpingitis of both tubes, and the appendages on each side were bound in inflammatory adhesions. I informed the mother and daughter that these organs could not be cured, and that they were not only a cause of increased suffering, but attended by some danger. The mother and daughter were both anxious that the operation should be performed. They called again, and in a few days the mother brought the daughter to the hospital, 725 Greene Avenue. It was deemed advisable to perform the operation as soon as possible. It took place December 13, 1888. The tumor was found to be a blood cyst of the ovary, developed from an endothelioma. This blood cyst was bound firmly by pseudo-membranous adhesions to the walls of the pelvis, so also was the other ovary. The tubes also gave evidence of long existing disease. The patient made an excellent recovery, and was able to be up in three weeks, free from pain, and every day seemed to grow stronger and better, and did not at the time have a return of the epilepsy.

As this operation seemed to be of such essential benefit, wishing to remove all trouble I passed the patient over to the department of general surgery for the depressed bone of the skull to be raised, several physicians whom she had consulted having considered this the cause of the epilepsy. The operation was successfully performed, January 25, 1899, and from it the patient made an excellent recovery, but after it the attacks of epilepsy seemed to recur, though they again gradually diminished in number. Certainly the patient was cured of her pelvic trouble, and to that extent her general system was benefited. But epilepsy is a disease or defect of the brain, and after we have removed what may be the exciting cause, the trouble is still there, as Hippocrates,[1] whom Fodéré[2] calls "le divin vieillard," says of epilepsy: "The truth is the brain is the origin of this affection as of all other great maladies."

When the ovaries are diseased their removal does good, but when the organs are normal, their removal can result in no benefit, but rather in harm to the individual. Professor Schroeder stated that he had operated twelve times for the removal of healthy ovaries for neurosis. I said in an article, 1893: "I denounce the removal of the uterine appendages for any cause, neurotic condition, or constitutional disturbance, or for any reason except incurable disease of the organs themselves; and when thus diseased they are a continual injury to the system, and their removal is a lasting benefit."[3] In the same article I said:[4] "Even if the epilepsy results from deep lesion of the nervous system, yet a disease of the uterine appendages will aggravate the conditions and be a source of increasing suffering, and there is no reason why a person should not be relieved as much as possible."

I further remarked, "pelvic disease may in some so disturb the nervous system as to cause some form of insanity;" but this can be only in those who have a tendency to or a pre-existing brain trouble. I continued: "The removal of the diseased structures will assuredly relieve the physical suffering of the patient in this direction, and there is no reason why sick women should not be relieved as much as possible. The same in cases of insanity, when the uterine appendages are profoundly diseased and are only a source of suffering and danger, is there any reason why they should not be removed?" I closed the article by saying, "I plead, in the interest of humanity, for these poor overburdened women."[5]

From *The Journal of the American Medical Association*, September 1, 1900, we see that this important

[1] New York Medical Journal, May 10, 17, 1890, p. 511; and Buffalo Medical Journal, November, 1892.

[1] "Les maladies sacrées."

[2] "Médecine légale," 1813, p. 17.

[3] In the Amer. Jour. of Obstet. February, 1888, vol. xxi., p. 158, I say: "I would not remove healthy ovaries for dysmenorrhœa, or any suffering in the regions of the ovaries. I would not remove them for epilepsy, believing the lesion to be elsewhere. . . . I would not remove them for mental or neurotic disease. I have never operated on a case but I had full and substantial reason to diagnose incurable disease of the appendages." I said again in the New York Medical Journal, May 10, 18, 1890, p. 511, "I make the 'uncompromising' sweep of excluding all cases from this operation except where there is hopeless disease of the organs themselves."

[4] The Medical and Surgical Reporter, Philadelphia, May 22, 1893.

[5] But I realize the difficulty as stated by some neurologists, and for their opinion I have the most profound respect. T. Claye Shaw says in St. Bartholomew's Hospital Report, vol. xxii., 1886, p. 105: "Many women are too violent to be examined, in others there may be danger of setting up delusions of a sexual nature."

subject was presented by several of the learned members before the association at its late meeting. Dr. G. H. Noble, of Atlanta, Ga., in an excellent paper put forth the question, "Do you regard malformations and traumatisms of the female genital apparatus as a cause of insanity?" He gives the reply of Dr. Maury, of Memphis, who has operated a number of times and who states that he could "not recall a case of mental recovery, and that his cases of surgical traumatism showed evidence of previous insanity." Dr. Noble quotes Hobbs as saying: "I have never yet seen a patient entirely relieved of a mental disease as the result of operative treatment." Dr. Noble closes his article with the timely words, "Have we the right to deny insane women the privilege their more fortunate sisters receive?"

Operative treatment in time might possibly save many who have a tendency to insanity. But this tendency in them and (because of this tendency) insanity may be excited by various adverse causes, physical or mental. Dr. Vander Veer, of Albany, answered Dr. Noble's question by saying that he did not believe traumatism and malformations contribute to insanity. How could we think otherwise when there are millions of women who suffer from these traumatisms who do not go insane? It is only those whose innate insanity is developed in connection with, before, or after the traumatism.

Dr. Carpenter, professor of nervous and mental diseases in Ohio Medical University, in his paper quotes Krafft-Ebing as maintaining that the influence of diseased generative organs in women should not be underrated as a physical cause of insanity. Dr. Carpenter adds: "It is questionable if medical knowledge and experience would justify operating on the defective classes. . . . All our asylums have representatives from these classes who have not only been not benefited, but in reality have been made worse by the operation."

Dr. H. A. Tomlinson, superintendent of St. Peter's Hospital, Minnesota, in a paper presented before the American Medical Association, September 3, 1899, tells us that in "only ten out of the four hundred and fifty women was there any exaggeration of the mental disturbance during the menstrual period, and only two complained of physical discomfort: two women in whom there was apparently a distinct relation between the menstrual disorder and mental disturbance. In both cases the uterus and ovaries were removed, and there was not only no improvement in the mental condition, but a distinct increase of disturbance after the direct effect of the surgical procedures had subsided, and more rapid determination of dementia followed the artificial establishment of the menopause. Many of the women have been operated on, and all needing local treatment received it, but in the majority of cases the relief of the pelvic disorder has been practically without influence on the mental condition of the women."

Dr. Tomlinson says finally: "We have not found that there is any particular form of insanity associated with pelvic disease. In fact, most of the cases, after careful examination and study in the hospital failed to disclose any evidence of severe pelvic disease, or any connection between the insanity and disease of the generative organs."

Dr. R. M. Bucke[1] reports the results of one hundred and ninety-five operations: "In three cases the patients died as the result of the operation, in nearly all the rest of the cases the physical health of the patient has been restored or greatly improved." As regards the mental health: "In thirty-nine cases the patients recovered from insanity. In thirty-two cases there has been improvement in the mental insanity of the patients. In thirty-five cases there has been no improvement in the patients' mental condition. So that seventy-two out of one hundred and six cases who survived the operation either recovered their mental health, or this was improved." The author remarks on page 11, "It is my opinion that very few of these cases would have recovered, or greatly improved if they had not been operated upon. Some of them who did well must have very soon died had no operation been done."

Dr. Bucke gives some most remarkable cases, for instance the following, the patients recovering their mental and physical health soon after the several operations: 1. Chronic mania three and a half years' duration, two cystic ovaries removed. 2. Chronic mania two years' standing, lacerated cervix repaired. 3. Chronic mania over seven years' duration, cystic ovaries removed and lacerated cervix repaired. 4. Destructive mania for five years, both ovaries removed—one a multilocular cyst, size of an orange, the other ovary adherent and atrophied. 5. Three years insane, ovariotomy and ventral fixation. 6. Chronic mania sixteen years' standing; ovaries enlarged and cystic, tubes adherent; removal of tubes and ovaries. 7. Delusional mania five years' standing: both ovaries removed, one a cyst of fifteen pounds. 8. Delusional mania two years' standing, trachelorrhaphy. Many other cases are referred to, all so successful that one is strongly impressed that those who are suffering and need an operation should be helped; yet the eminent authority, Dr. Percy Smith, of London, says, "he could not accept the views held by some American gynæcologists that the uterine appendages should be removed in insanity." Still we see that a certain number of patients are relieved of at least a portion of their distress. F. Claye Shaw in 1886,[1] speaking of one of his patients who was more violent during the periods, said: "I think the operation of oöphorectomy would have much relieved her symptoms." Dr. Smith stated that "in asylums in only a small proportion of cases in females was the mental disorder due to disease of the sexual organs."

I believe in no case is mental disease due to a disease of the sexual organs. Dr. Holmes, ex-president of the Canadian Medical Association, years ago came to the conclusion that "puerperal insanity is nearly always dependent upon some lesion of the generative organs." Yet there are millions of women who have lesions of the generative organs and no tendency to insanity.

Dr. Kellogg is of opinion that "pelvic disease in women may be, and at times is, the cause of insanity, and that the removal of the pelvic disease by operation is often followed by a relief or cure of the mental alienation."

This subject was presented before the British Gynæcological Society, January, 1900. The president, Dr. H. McNaughton Jones, made the address on the occasion: "The Correlation between Sexual Function, Insanity, and Crime." Dr. Jones is authority on all gynæcological questions. His work on "Diseases of Women" is one of the best published—comprehensive, accurate, and reliable. He scans every fact and brings it in line for medical instruction. In his address before the Gynæcological Society, after presenting the many different views, he says: "Personally I at present take the view that, in the great majority of cases in which there are gross lesions of the sexual organs present in insane women, and even when the lesion has preceded the insanity, there still has been pre-existing to the lesion what Robert Barnes well calls 'an antecedent nervous condition as a predisposing factor.'"

Let us glance for a moment at some of the causes of insanity as presented by various authors. E. Es-

[1] American Journal of Insanity, July, 1898, No. i., vol. v.

[1] St. Bartholomew's Hospital Report, vol. xxii., 1886, p. 105.

quirol in 1858 published a learned work on "Maladies Mentales," and in it he states that "the causes of mental alienation are as numerous as various." This work, he says, was the result of forty years of study. But this great scholar not being fixed by the fundamental fact that the brain is the organ of the mind wanders in much mystery, and gives a countless number of theories and untenable suppositions as the causes of insanity. They may be interesting, but lead only to more confusion in the scientific discussion of this most important subject.

His first cause of insanity is "climats," saying: "Cold climates are not those which produce le plus de fous, mais bien les climats tempérés." Then we might expect an army of insane people in all temperate climates. According to the table he gives, the greatest number of insane people are in May, June, July, August, and September.

Third cause of insanity, "âges." Esquirol says of insanity in infants that some vice of conformation or infantile convulsions may throw them into imbecility and idiocy; of the insanity of puberty, that in the young insanity may have a rapid march; that mental alienation may be divided relatively to age—imbecility for the infant, mania for the youth, melancholy for the aged, and dementia for the advanced age.

We do not find that the young or old as they approach any particular age have any special tendency to insanity.

Fourth cause of insanity, "sexe," as if mental disease was any more confined to sex than are chills, fevers, consumption, etc. The author says: "Cœlius Aurelianus asserted that women were less subject to insanity than men." This, says the author, was true at the time of Cœlius, is still true in Italy and in Greece, but in the north of France the contrary condition exists ("le nombre des femmes aliénées y est plus considérable que celui des hommes"). He tells us from 1745 to 1775 Raymond did not find the difference between the two sexes among the insane at the Hospital of Marseilles, and that in 1786 Tenon found there was almost an equal number among the men and the women in the public and special houses of Paris; in 1802 Pinel established the difference of one man to two female aliens in comparing Bicêtre to La Salpêtrière; that in 1807 and 1810, among the hospitals of the principal cities of France, there were found about six thousand aliens, five men to seven women.

The director of the Hospital of St. Luke reported that he received annually in the hospital nearly one-third more women than men. In the hospital of Berlin the proportion of men to women is one to two. In the hospital of Pennsylvania the proportion is the reverse, one woman to two men.

So we might go on in these endless endeavors. We would find continually varying proportions. Insanity is not controlled by sex, or necessarily found proportionally more in one sex than in the other. Just as well raise the question in regard to scarlet fever, how many female children have it and how many male. Richard Grundy[1] tells us that "Dr. Thurman, of York, England, and Dr. Jarvis, of Dorchester, Mass., agree that Esquirol's conclusions are based upon imperfect premises. Their investigations lead them to the conviction that 'males are somewhat more liable to insanity than females.'" He says: "The statistics of seventeen asylums in the United States show the admission to be in the following proportions: 38,416 patients, there were 20,233 males and 18,213 females."

F. E. Fodéré[2] says: "Among the many maniacs confined to my care a great number are of the female sex."

Esquirol gives the fifth cause of insanity, "temperament," and says: "The tempérament sanguine is one of predisposition to mania. The nervous and lymphatic temperament is favorable to the production of mania and monomania. Of two hundred and sixty-five aliens Haslam found two hundred and fifty whose hair was dark, and sixty who had light hair. In Pennsylvania Hospital out of seventy aliens only one had light hair, fifty-six had the eyes blue or light."

What has the color of the hair to do with insanity any more than the shape of the nose or size of the ear? Yet the author on page 40 says: "In general, those who have the hair dark, who are strong, robust, of a sanguine temperament are the maniacal, furious, the march of their insanity is more acute. Those whose hair is blond, who have blue eyes, a lymphatic temperament, become maniacal and monomaniacal, their *folie* passes easily to a chronic condition, and degenerates into dementia."

Sixth cause of insanity, "professions," manner of living. Those who give themselves up to study present a condition favorable to the development of mental alienation. He quotes Dryden as saying that "men of genius and fools are very near together," and says: "The frequency of *folie* always corresponds with the professions which make men more depend upon social vicissitudes, that Aristotle demanded to know why great legislators are all melancholic;" and M. de Humboldt is said to have seen very few aliens among the savages of America. Carr says he rarely saw one in Russia. Esquirol says in France there are less "*fous*" in the country than in the cities; that in England, where we find united all the excesses of civilization, *folie* is more frequent than elsewhere. The badly assorted marriages, or those contracted between parents above all in families in which there is an hereditary disposition to insanity, the habits of alcoholic drinking, etc., are the causes which multiply insanity in England. He quotes J. J. Rousseau as saying: "Without doubt civilization occasions some maladies and augments the number of others."

Is it reasonable to suppose there are proportionally more insane people among the educated, and among those most advanced in civilization, than among the uneducated and uncivilized? We have no means of knowing the number of insane people among the uncivilized nations, but we do know that the brain, like every organ in the body, will be more healthful by judicious and regular exercise. Exercise tends to balance the circulation and prevent localized congestions.

The author next tells us, "that excesses in eating should be placed among the causes of mental alienation." On page 50 he speaks on the influence of marriage upon the production of mental alienation. Marriage in itself is calculated to produce contentment, harmony, and happiness. Even if the marriage should prove unhappy, and there may be thousands that do, yet the parties do not necessarily become insane; and if insanity should occur in a happy or unhappy marriage, it is because there is a previous disease of the brain, or hereditary tendency thereto.

Seventh cause, "passions." Esquirol says: "Those which produce most frequently insanity are pride, fear, fright, ambition, and distresses from financial reverses." The author adds that heredity is the most ordinary predisposing cause of insanity, that children who are born before the parents become insane are less subject to mental aberration than those born afterward. The author continues: "Menstruation often produces mental alienation; leucorrhœa also insanity. Pregnancy is a cause of insanity, but sudden or violent *folie* is more frequent after confinement, and during the period of nursing (l'allaitement). At La Salpêtrière of six hundred insane women fifty-two had

[1] Columbus Review of Medicine and Surgery, August, 1860, p. 69.

[2] "Traité de médecine légale," 1813, vol. i., p. 209.

lost their reason after l'accouchement or lactation. Some females become aliens after each confinement."

Menstruation, pregnancy, and lactation are all normal functions and are not a cause of insanity; but, from disease of the brain, a woman may become insane while performing any of these functions.

Esquirol gives beautiful lectures on all the foibles of humanity, placing them as the causes of insanity, forgetting that there are millions who have all these foibles and do not go insane. He says: "Blows upon the head, even in earliest infancy, predispose to insanity." What child does not get repeated blows upon the head—do all become insane? He says: "First dentition if causing convulsion in infants predisposes to insanity."

He next gives the republican form of government as most favorable to the production of insanity, then names a number of affections and passions that lead to insanity, making almost every passion and every incident in human life a cause of insanity. Esquirol's work, "Les maladies mentales," is almost universally quoted, but probably it might have been better if the learned author had written not quite so many pages, or if he had prayed the beautiful prayer with which Benjamin Rush opens his book.[1] Rush says: "I humbly implore that Being whose government extends to the thoughts of all his creatures, so to direct mine, in this arduous undertaking, that nothing hurtful to my fellow-citizens may fall from my pen, and that this work may be the means of lessening a portion of some of the greatest evils of human life."

Dr. Benjamin Rush gives many causes mentioned by Esquirol. Rush's book was written in 1812, Esquirol's in 1858. Dr. Rush says: "I shall now mention climate, state of society, form of government, revolutions, and religion." He makes the same quotations from Dryden, Humboldt, and several others as appear in Esquirol's book. Dr. Rush says: "A predisposition to madness is said to be connected with dark-colored hair. Mr. Haslam informs us that this was the case in 205 out of 265 patients in Bethlem Hospital. Of nearly 70 patients who were examined in our hospital, in the year 1810, with reference to this fact, all except one had dark-colored hair. In the month of April, 1812, I requested Dr. Vandyke to direct his inquiries more particularly to the color of the eyes in the maniacal patients in our hospital, and he discovered that 56 out of 79 of them had light-colored eyes, of which number but 6 had fair hair. Women in consequence of the greater predisposition imparted to their bodies by menstruation, pregnancy, and parturition are more predisposed to madness than men."

Here I feel I must, in the cause of truth, differ from this great man. Neither menstruation, nor pregnancy, nor parturition predisposes to madness. Dr. Rush continues: "In St. Luke's Hospital in London, the proportion of women to men who had been admitted in a given number of years, is in the ratio of three to two. But this disproportion of women to men who are affected with madness is by no means universal. In a hospital for mad people in Vienna, 117 men were admitted in a given number of years, and but 94 women. In a hospital of the same kind in Berlin, twice as many males were admitted in a given time as females. More of the former than the latter have been admitted into the Pennsylvania Hospital. Certain climates predispose to madness, also certain forms of government."

Mr. Forbes Winslow[2] on many points agrees with Esquirol. He gives the "seasons" as a cause of insanity, and follows Esquirol in supposing there is more insanity among women, saying: "In England, and I believe in most other countries, insanity is more prevalent among women than among men. . . . The greater liability of the female sex to become insane is associated with other peculiarities worthy of consideration."

It is not "sex," that causes insanity, but the disease of the brain in either sex. On page 227 he says: "Domestic cares are the chief cause of insanity in women." Millions of women undergo the greatest labors and the most taxing domestic cares and show no tendency to insanity; indeed, it is not those who have the most domestic care who go insane. Mr. Winslow says, page 228: "Of course woman from her formation and the duties she has to perform in life is liable to become mentally unhinged." Then woman is imperfectly made, if, from her formation and duties, she is "liable to become mentally unhinged." Such an assertion is almost a libel on the Creator's wisdom.

Winslow says: "Drink is at the head of the real causes both of insanity and crime." Then he gives the moral and physical causes of insanity—pecuniary difficulties, domestic troubles, loss of relations, mental anxiety, overwork and worry, intemperance, accidents, sunstroke, privation, starvation, sexual excesses, pecuniary anxieties, and a host of other things.[1]

Winslow continues: "Among the tendencies that serve in fostering this malady, European civilization shows itself as one of the most potent. Mental alienation is scarcely ever met with among the Asiatics, or Africans, or among the savages of America. The number of insane people is largest in those countries where the most liberty is allowed. What we call European manners, social conditions and progress offer conditions which can be accepted only at the risk of our health and morals. At the present day there is more insanity than in the middle ages, there is less in Russia than in England and France, and there is very little among the Turks, Arabs, and in the uncivilized parts of the world. In those parts of the world where the mind has but little to occupy itself, there is less likelihood of mental derangement."

The tendency of all advancement in civilization, with improved conditions of public health, should tend to lessen the number of insane people. Dr. Henry Maudsley[2] says: "A higher mental development must tend to prevent insanity. The intellect suffers more from rusting and disuse than it does from its utmost use. . . . One fact," says he, "which the statistics of insanity in England has clearly shown is that the purely agricultural counties furnish the largest percentage of insanity in proportion to the population; that is to say, there is more madness where there are the fewest ideas, the simpler feeling, and the coarsest desires and ways."

In Pinel's great work, second edition, 1809,[3] we find given (page 11) the following causes of insanity: "Age, sex, climate, the manner of life, certain epochs

[1] "Medical Inquiries and Observations upon Diseases of the Mind," 1812.

[2] "Mad Humanity," by Forbes Winslow, London, 1898.

[1] Considering the vast number of causes of insanity, and the infinite number of cases, one will appreciate the kindly consideration of the superintendent of the Provincial Lunatic Asylum, of Toronto, Canada West, in planning for or thinking of the accommodation of the increasing crowd. He says: "Now if any one of these agencies may be regarded as adequate to the overthrow of reason how many lunatics should this province contain? Intemperance alone would people fifty asylums as large as our present one. Jealous husbands and wives would probably fill thirty. Political excitement would tenant a madhouse in every county and one of superior class and size in the metropolis. Religious controversy would send in half the clergy of this province, and large detachments of the congregations. Slander, excessive study, remorse of conscience, would leave few in Canada at large."

[2] "The Pathology of the Mind," 1896, p. 29.

[3] "Traité médico-philosophique sur l'aliénation mentale." Par Pinel, professeur à l'école de médecine de Paris, et médecin-en-chef de l'hospice de la Salpêtrière.

in the life of woman such as puberty, pregnancy, childbirth, et ce qu'on appelle l'âge critique.

On page 418 he says: "The most ordinary physical causes are: The original disposition, the suppression of periodical discharges, accidents during childbirth, the abuse of alcoholic liquors, blows upon the head. The moral causes: Terror, disappointed love, reverses of fortune, domestic trouble, and religious excitement, or exalted devotion."

Aretæus, who lived in the time of Vespasian (Homer and Hippocrates being the only authors he quotes) gives as causes of insanity: "Drunkenness, excesses of the table, venereal pleasures, or anything that causes obstruction to an habitual excretion. Occasionally women will become affected with mania from amenorrhœa."

Dr. T. S. Clouston, superintendent of the Edinburgh Royal Asylum, in his learned work[1] makes rather a new departure in regard to the technical names of insanity. He speaks of syphilis as a cause of insanity, calling it "syphilitic insanity." Syphilis in the system must affect the brain, as it does every organ in the body, but why call it "syphilitic insanity"? The author places alcohol among the most common of all causes, denominating one form "alcoholic insanity," and says: "There are few of the unfavorable conditions of life that cause more human degradation than the excessive use of alcohol." Of "rheumatic choreic insanity," he says that in many cases rheumatism was the true cause of both the chorea and the insanity.

He next gives, page 521, "uterine and amenorrhœal insanity." Can we admit such a technical name as scientifically accurate? With this mode of nomenclature we may have an infinite number of forms of insanity. The author speaking of "disorders of menstruation and their relation to insanity," says: "Two kinds of insanity resulting, acute mania and melancholia." Unnumbered women have disorders of menstruation without the least tendency to either of these two forms of insanity. The author next tells us that "disturbed menstruation is a constant danger to the mental stability of some women"—only to those who have some brain lesion or disease, or an inherited tendency thereto. The author says: "The constant difficulty the physician has, is to know whether the disordered or suspended menstruation is a cause of insanity or a symptom."

It is neither a cause nor a symptom. The cause of insanity is some disordered condition of the brain. Suspended menstruation may come from various causes of ill health. Many women have disturbed or suspended menstruation without the least indication of insanity, yet the author continues: "Insanity in some few cases actually results *de novo* from this as an exciting or predisposing cause."

Insanity comes only from some abnormal condition of the brain, therefore we cannot see that these cases can be termed "uterine or amenorrhœal insanity."

The author tells us, "the risks to the mental functions of the brain from the exhausting causes of menstruation, maternity, and lactation, from the nervous reflex influences of ovulation, conception, and parturition are often enormous."

Might we not just as well speak of the "enormous and exhausting causes" of continued breathing, the incessant action of the heart, and the unparalleled demands of the continued function of digestion, the constant demand for nutrition of the whole body, and of how they are "risks to the mental functions of the brain"?

All these are natural physiological processes, and certainly can be performed without any risks to the mental balance.

[1] "Clinical Lectures on Mental Diseases," T. S. Clouston, fourth edition, London, 1896.

Next we have in large type "ovarian insanity (old maid's insanity)." The author observes: "There is a somewhat ludicrous form of insanity that Dr. Skae called 'ovarian,' and more correctly I think, 'old maid's insanity.'" Both of these terms seem exceedingly inappropriate and unscientific. Dr. Clouston adds: "The disease usually occurs in unprepossessing old maids. The ovaries are not disturbed in function or diseased in structure."

Of insanity of masturbation, Clouston says: "The subjects will be found to have had early indication of brain disease, or a neurotic heredity." This explains why they are insane, and probably gives a reason for the vice named.

In lecture XV. on "puerperal insanity, lactational insanity, the insanity of pregnancy" the first sentence is: "Childbirth, nursing, and pregnancy in women are liable to act as exciting causes of mental disease." Can we accept the doctrine that normal functions act as exciting causes of mental disease? I challenge the whole theory. Then all women should be shut up in some immense La Salpêtrière.

The author says: "The regular performance of the reproductive functions is of the highest importance to the mental soundness of the female. Disturbed menstruation is a constant danger to the mental stability of some women." Aretæus said: "Mania from amenorrhœa." Pinel repeated that "pregnancy, childbirth, and suppression caused insanity." Krafft-Ebing, in conservative words, tells us the same. Esquirol more plainly declares: "Menstruation often produces mental alienation. Leucorrhœa also causes insanity."

Neither menstruation nor leucorrhœa has the power to change the structure or condition of the brain, therefore they cannot be a cause of insanity. It can also be shown that the brain affects the genital and other visceral organs more than these organs or their functions affect the brain. We see how the brain may quicken the heart's action, make more rapid breathing, hasten the circulation—sending the blood bounding with increased quickness, the flush on the face, the heat and excitement of the whole system. The mental agitation increasing, the heart with its immense machinery of muscles and multitude of blood-vessels may be overpowered, give way, and by the dominating power silenced into the stillness of death.

Continually we are realizing how the brain will disturb the process of digestion, and that mental excitement may take away the appetite, interfere with the secretion of the gastric juice, the bile, the secretion from the spleen, or so change the lacteal secretion as to produce in infants convulsions and death.

Great mental excitement many times causes excessive menstruation. It may even suspend menstruation. It may cause premature labor. A mother said goodby to her dying babe, and walked into the next room. Her great grief had stimulated to action all the immense muscular structure of the uterus and the whole system in sympathetic action, and she thus brought forth the child before its time. "When Phinehas' wife heard that her father-in-law and her husband were dead, she bowed herself and travailed; for her pains came upon her." It was grief in the mind that was producing the revolution in the system.

"Puerperal insanity." There is no insanity which should be regarded as necessarily belonging to the puerperal state. It is only possible that insanity may be developed at that time, and we will find the subjects of it have some inherited insane neurosis. The author says: "The pains of labor, the mental excitement and stress, the maternal emotions, the sudden diversion of the stream of vital energy from the womb to the mammæ." All this is normal. The author well adds "acting on an unstable brain hereditarily." That is the secret—acting on an unstable brain. And

the author further emphasizes the fact by saying: "I know a woman (page 552) K. B——, who had six attacks of puerperal insanity, having one after the birth of each child." We see the cause was in the patient. Another woman may have had twice six children and no attack of insanity. The author then gives another proof of the same—what he calls "a typical case of puerperal insanity. K. G——, æt. twenty-three; sister and aunt had been insane. The patient had pains in the head before delivery. On post-mortem, brain intensely congested." Here was the reason of the insanity, the hereditary tendency and the congestion of the brain.

Normal labor makes no insanity. Scripture says: "Thou art He who took me out of my mother's womb." Infinite wisdom devised the plans and fixed the laws, so there can be no imperfection by which insanity should ensue.

Clouston in his work on page 560 heads the chapter, "Lactational Insanity," and opens by saying: "Nursing in woman is a cause of mental disease sometimes." Lactation is a normal function, not necessarily attended with any ill health, nor does it cause insanity or mental disease. Women become insane during lactation only because of some brain lesion. As confirmatory of this, the author, on the next page, gives "a typical case of lactational insanity." The patient "had headaches, noises in the ear, giddiness, flashes of light before the eye." All these are indications of some local disease of the brain.

The next chapter is headed "The Insanity of Pregnancy." The first sentence is: "Few women carry a child without being influenced mentally thereby in some way or another." They are influenced mentally by the coming joy, the added responsibility, and how best to care for and promote the happiness of the little one. The author continues: "In this state (pregnancy) many women have endless caprices, unfounded dislikes, causeless weeping and laughing, stealing, lying, etc." I can't see that unfounded dislikes, stealing, and lying are symptoms of "this state." Yet the author asserts that "a considerable number of women are mentally unsound during pregnancy." All this may be true of women in the Royal Asylum of Edinburgh, but it is not so with women of the outside world. If insanity results from pregnancy, then there has been a sad failure in the formation of women. Insanity may be developed during pregnancy, but only in those women who have some insane neurosis. The author, as if to prove this point, says: "I have a patient K——, who has been five times pregnant, and five times insane, each time during pregnancy." Many other women may be twice five times pregnant, and yet not one time insane. The author further substantiates the fact by saying: "I had one patient who had six different attacks of insanity, two of pregnancy, two puerperal, and two of lactation—in each she was most determinedly suicidal and homicidal, strangling and killing her first child, and attempting at least six different times to take her own life."

The insanity in each individual case results from a state of the brain, not from the physiological functions the patient may be performing. As further to prove this point, the author gives two more instances of puerperal insanity. "One, K. M——, thirty-four years old, with an *insane heredity;*" the other "K. O——, thirty years old, and *hereditary history of insanity.*"

In lecture XVI. on "The Insanities of Puberty, Adolescence, the Developmental Insanities" the author says: "Puberty is the first really dangerous period in the life of both sexes as regards the occurrence of insanity; but is not nearly so dangerous as the period of adolescence a few years afterwards, when the body as well as the functions of reproduction have more fully developed."

Neither puberty nor adolescence is a dangerous period, and at neither period is there in the normal processes any tendency to insanity. Nor are there any insanities that are an outgrowth of, or that necessarily accompany, physiological development, which should be called, "developmental insanities." Would not this put a note of interrogation as to the wisdom of our formation? It is only that insanity may occur during these periods in those who have already disease of the brain, or an inherited predisposition thereto. The process of normal development gives no "peril to the healthy mental balance."

The author next says: "The following is one of the most characteristic cases of early insanity of puberty I have met with: K. P——, aged eleven and one-half years. His mother had an attack of puerperal insanity (mania), and attack of acute delirious mania, and she died melancholic. An elder brother at the age of nineteen had adolescent insanity (mania), and became demented. A sister became insane, and another sister was devoid of all moral feeling or self-control."

Does not all this explain why the boy had insanity at puberty, or at any other period? It was an inherited predisposition; and from such cases the conclusion should not be drawn that "puberty is a dangerous period as regards the occurrence of insanity." Puberty has nothing to do with the origination of insanity. It was an inherited mental disease in the boy, and in consequence, as is stated, he had five attacks; yet the author says: "I look upon such a case as an example of the evolution of a new function." Does nature then evolute a new function by producing, or accompanying it with, 'attacks of insanity"? The author incidentally remarks it was "a brain strongly predisposed by heredity to insanity." This explains.

Dr. Clouston next gives a remarkable case of adolescent insanity, as he says, "terminating in recovery." The following is the history, and in the same line are revealed the fundamental facts: "The boy had neurotic heredity, his mother having had puerperal mania after the birth of almost every child, his father having been nervous, two sisters and one brother having attacks of mania."

Does not such an heredity sufficiently explain the "adolescent insanity"? On the next page the author says of this patient: "His whole mental state suggested secondary dementia. . . . It seemed to be in truth a toss up between recovery and dementia. . . . Fortunately," continues the narrative, "the recuperative power of his brain and constitution prevailed. . . . In six months from the commencement of his illness he was quite well in mind and strong and stout in body." When I had read thus far, I made the note: The boy will probably have "adolescent insanity" by the time he is forty or fifty years of age. The narrative continued: "He became insane in eighteen months, recovered, kept well for a time, then had another attack of mania, which ended in secondary dementia."

It was clearly a case of hereditary insanity. The author says: "Another case of adolescent insanity, heredity very neurotic, mother very nervous, aunt insane, and father drunken. He sank into dementia in about two years."

Of a similar case the author asserts: "There seemed absolutely no exciting cause whatever for the attack but the completion of the period of adolescence"; yet Dr. Clouston states: "He came of one of the families of the fishing village of New Haven, that must have had some very unstable mental stock introduced into them many generations since, and in many of which now there is an enormous amount of insanity or epilepsy."

Why attribute this case of insanity to "adolescence," when here is the efficient cause? Adolescence is not a cause of insanity.

Causes of insanity as presented by Dr. Regis.[1] Dr. Regis says: "There exists in no part of the economy a sympathy more intimate than that which connects to the nerve centres the organs of generation, and it is not rare to see the processes physiological and pathological of these organs determine some intellectual disorders which go even to madness or insanity, and in particular à la puberté, à la menstruation, à la menopause et aux affections locales de l'uterus et de ses annexes."

I do not believe the physiological processes or functions of the organs of generation ever cause madness or insanity; and not one developmental process has a tendency to, or does lead to, insanity. The insanity is from some other cause.

The author says: "The physiological disorders connected with puberty are various." He then gives a long list, adding: "Above all the young boys are awakened to a very marked propensity to suicide, wicked tendencies, impulses to robbery, to incendiarism, and to murder." Continues the author: "Other phenomena more grave may join these and lead to a veritable state of mental alienation."

Puberty is normal development; there can naturally be no insanity or psychological disease connected with nature's normal processes.

Next Dr. Regis speaks of menstruation (folie menstruelle) insanity, and says: "With most females, even in physiological condition, the return of menstruation is accompanied each time by trouble, intellectual and moral." Adding: "During menstruation females are subjected to singular caprices, fantastic tastes . . . some have a spontaneous tendency to wrongdoing, and give themselves up to irresistible impulses."

All these views may seem to be very scientific as one passes through the wards and immense halls of La Salpêtrière. But outside of that hospital there is a great big world, and there are untold millions of women who pass through the menstrual period without any of these psychical symptoms, or any form of menstrual insanity. Normal, healthful menstruation is accompanied by none of these supposed changes. I have seen hundreds of women pass through this period without the least pain or disturbance, mental or physical. I have seen thousands of young girls, at different schools and colleges, going regularly through the function of menstruation without the least trouble, intellectual or moral. Nearly ten years I spent in colleges for young women, over three years I was a student, and six years a professor of physiology and belles letters, and subsequently for many years had charge of a young ladies' boarding-school. Thus many thousands of young women came directly under my observation, and never had they thought of such a thing as intellectual or moral trouble during the period of menstruation. With hundreds and hundreds of young girls each year menstruation passed off so quietly that it was not thought of or recognized, nor was the time of its occurrence known. The young ladies continued just the same at their studies, and were apparently just as ambitious to excel, and answered just as brilliantly in their recitations.

Dr. Regis says: "Authors have reported a certain number of cases of insanity connected with the menstrual period, which can leave no doubt of the reality of its existence."

If there were many more cases cited, that would not prove the rule, and no such conclusion should be drawn. They were all insane people. If normal menstruation had a tendency to produce insanity we might well doubt and fear the results of any normal function of the whole body.

[1] Journal de médecine de Bordeaux, vol. xiii., 1884, p. 413. Also, "Dictionnaire encyclopédique des sciences médicales," Paris.

The author continues: "As to the troubles of this function, and notably the suppression of menstruation and dysmenorrhœa, their action upon the intelligence is more evident and more frequent still, and it leads also frequently to folie, to theft, to incendiarism, to homicide, to periodic dipsomania, but above all there is the impulsion to suicide which predominates in this variety of alienation."

The author quotes Esquirol. As H. R. Storer[1] says: "Each successive text-book has repeated the errors, or many of them, of its predecessors."

In my large and extensive practice of over thirty years, though I saw many sick women suffering from menstruation, which most frequently I found a symptom of more serious conditions, yet I never found, with the exception of the four cases referred to, one woman who gave any indication of the least mental or intellectual trouble.

"Folie de la menopause." Dr. Regis says: "The menopause, so justly called the âge critique, is a period dangerous to pass through for many women, and it is very frequently the occasion of perturbations intellectual and moral, and psychological changes which can go even to madness or insanity. . . . It is not doubted that among the most part of women, normal or not, the time critique leads to revolutions more or less profound of the organism, and that among some these modifications of intelligence attain the proportion of true insanity."

The menopause is not a dangerous period to pass through, many women pass through it without the least disturbance. The author continues: "Above all there is a tendency to dipsomania, to theft, to homicide, to incendiarism, but still more to suicide."

This is almost a libel on the natural formation of one-half of the human race, that such manifestations should take place in natural physiological processes. Can any one recognize it as reasonable that there is a tendency to madness in the normal suppression of menstruation? No function when it is normal, or the normal change of the system, goes naturally to insanity.

The author next speaks of the local affections of the uterus and the uterine adnexa, saying: "If the physiological processes which have for their point of departure the organs of the genetial organization are frequently the object of intellectual troubles, the maladies of these organs are perhaps more frequently so."

I have seen many women with the worst forms of disease of the uterus and the uterine adnexa and not the least indication of intellectual disturbances. Among all the women I have attended for diseases of the genetial organization, I have found only four with a tendency to insanity, and they had not the worst forms of these diseases. Besides I have reason to believe they had manifestations of insanity before the development of these troubles.

Causes that by changing the structure of the brain may produce insanity. Recognizing that the brain is the organ of the mind, and that abnormal conditions or diseases of the brain are the causes of insanity, our next question is, What are some of the causes that will more directly produce these abnormal or diseased conditions in the brain structure? Such morbid changes, however produced, will be found to be the true causes of insanity.

I will name first heredity. Heredity may change the normal structure of the brain, producing permanent defects and degenerations. Heredity determines, in a large measure, the character, form, power, and constitutional tendencies of a child's brain. Mental defects in the parent, insane neuroses, or neurotic tendencies will leave their mark and impress on the young brain, probably producing various tissue

[1] H. R. Storer · "Insanity in Women," 1871, p. 27.

changes. While a good heredity may give a breadth, a light, a clearness, and a joy to this wonderful formation, a bad heredity will stunt it, darken it, make its nature less fine, and leave upon it its sad impressions and imperfections. Children are what their parents are. From whom else can they get their physical formation, or constitutional tendencies, or their make up? They partake of the conditions of their parents, inherit their physical and mental characteristics, and their defects.

These physical and mental defects may decide the character of the descendants. A parent may have untoward conditions from unhealthful living or previous inheritance, and the children will take on these conditions. A violation of the laws of health, in time, makes physical changes in the constitution of the parent. These physical changes or degenerations of one kind or another the children inherit.

Whatever disease or ailment our parents or ancestors may have, a tendency to it will be reproduced in the descendants. The condition of the brain of the parent or any changes in it from untoward circumstances may, in the child, become a constitutional imperfection. Scripture says: "The fathers have eaten sour grapes, and the children's teeth are put on edge." Other momentous words are: "The sins of the parent are visited upon the children to the third and fourth generation." Hippocrates wisely said many years ago: "Where is the malady with which the father or mother is afflicted that affects not the children?" And speaking of epilepsy, he says: "It is as the other maladies, by heredity."

The peculiar make-up necessary to produce any disease may be given by heredity. Thus from inheritance some brains are naturally better than others, have less liability to disease, and are less predisposed to abnormal conditions. So some, by inheritance, have better and stronger lungs, healthier hearts, and stomachs less predisposed to disease. When the lungs are small and contracted, slight causes may bring on disturbances, and induce most serious conditions. Hearts that are feeble in their action, one part or another being diseased or defective, may even from slight excitement have most serious results, as stomachs naturally predisposed to disease may have most distressing forms of indigestion.

A tendency in the parents to disease, or any evil predisposition may be inherited, as one auther says: "I know now the history of one family in which there has been insanity for five generations, and of another family in which it has been for four generations."

The records of all insane asylums show that one-third or one-half of the insane patients have hereditary taint of insanity. If the true history could be ascertained, probably it would be found that all have this taint; and probably the reason why there are so many insane persons in the various asylums in the world is the propagation of this insane neurosis. It may skip a generation, but it is still there. It is a cause that always operates. Moreau de Torey says that "nine-tenths of the cases of insanity come from inheritance." Dr. Edward Jarvis[1] said: "According to the British reports, twenty-two per cent. of all whose history could be ascertained, owe their lunacy solely to hereditary taint." Pinel said in 1809: "In many successive generations some one of the members of certain families have attained this malady."

Henry Maudsley says: "The insane neurosis, which the child inherits in consequence of its parents' insanity, is as surely defect of physical nature as is the epileptic neurosis to which it is so closely allied. Past all question, it is the most important element in the causation of insanity."

A second cause of brain injury that may result in insanity is: "The use and abuse of alcoholic liquors." This is universally given as a cause of insanity. It causes insanity by changing and injuring the brain structure. Prof. Charles L. Dana in his excellent work[1] says on page 25: "Excessive indulgence in alcohol is a most prolific cause of nervous disease." An editorial in the *British Medical Journal*, page 848, 1900, says: "Alcoholism is responsible as an etiological factor for twenty-five per cent. of all male cases of insanity admitted to our asylum."

There is a large record that cannot be put down, how alcohol is silently doing its work of evil, poisoning and making the most deleterious changes in the brain structure. A few years ago I was making microscopical investigations in the minute anatomy of the pathology of the kidneys, and I clearly saw how during life the millions of fine cilia were destroyed and rendered inactive in those who habitually use alcoholic drinks. In the same manner the fine structures of the brain may be injured and made inactive. Alcohol hardens and deadens the wonderful complexity of fine fibres, so that they cannot respond with their more than electric quickness and brightness; and an untold injury does it do to these marvellously complex structures, the convolutions of the brain. We cannot weigh or measure the immensity of these injuries.

Alcohol has its deleterious effect upon all the vital organs, and, in a measure that we cannot conceive of, disturbs the secretions and excretions, and thereby does direct and indirect damage to the whole system. It benumbs the brain, deadens the perceptions, and no child of a drunkard can be as bright as he or she otherwise would be. The drunken man has not his normal mental faculties. As one says: "Drunkenness, a brief chronicle of insanity, winding up with a temporary dementia." Benton said: "If a drunken man gets a child, it will never likely have a good brain." One of the leading physicians in America showed by his statistics that "out of three hundred idiots, whose history could be traced, one hundred and forty-five were the children of drunken parents. . . . I may state that quite thirty per cent. of lunacy in all parts of the universe originates in habits of intoxications."

But the most serious of all: We must recognize the great facts of physiology—children take on the then conditions of the parents. The temporary condition of either one may affect the child. The father is in a drunken stupor, this "temporary insanity" is transmitted, not the otherwise brightness of his ordinarily active mind. Yesterday, as I hastily passed along the street, on the pavement was lying a man in a dead drunken stupor. I had never before had the opportunity of looking into the face of a man while drunk, so by a hasty glance I learned all I could. The head was lower than the body, the face red and purplish. His brain was wonderfully shut up and benumbed in this insanity of intoxication. The child begotten has little brains, can't have much vigor of constitution, is a true impress of this temporary dementia, and notwithstanding the public-school training the child may still be stupid, ignorant, and with an unsteady mental balance. Unnumbered instances —how many thousands of children—are thus injured! Deprived of their natural birthright, their rightful inheritance, losses of inestimable value which time nor eternity can make up! The light they might have had, the clearness, the broad comprehension, where there is now darkness and an inability or imbecility. What a devastation! A consideration of these things is the greatest and most powerful lecture that can be given against drunkenness. It is a crime against their own children, and it is the destruction of future generations. The London *Lancet* in an editorial (August

[1] Norfolk Medical Society, Massachusetts, May 14, 1861.

[1] "Text-Book on Nervous Diseases," 1897.

11, 1900, page 411) said: "The intoxication of married couples on their wedding night has been believed to result in the production of offsprings suffering from imbecility or other forms of cerebral disease." Still goes on the injury to the bright spirits that should come without a flaw, stain, or drawback.

Considering all this, is it any wonder that insanity is on the increase, and that the children of drunken parents go insane, or are in a measure idiotic? All of which tells on the advancement of the human race, on the country's resources, and on the history of the world.

The third cause of deterioration of the brain, and indirectly tending to produce insanity, is the condition of the stomach and the state of digestion. If the digestion is not good, not so good nutrition is carried to the brain, the brain cannot be as well nourished or make as good tissues; and the results of this continued indigestion may, and gradually does, change the structure of the brain. The brain cannot be as sound or healthy, and thereby insanity may ensue.

As to the "correlation of the genital organs and functions in women with the brain or with insanity," there are other organs in the body that more decidedly and more directly affect the condition and health of the brain, and produce more marked anatomical changes, and more serious results than can possibly come from the sexual organs and their functions.

Fourth cause: An abnormal and unhealthy condition of the general system. Thus any organ in the body may be more or less diseased. Ancient physicians seem to have caught a glimpse of this subject when they speak of splenic difficulties, etc. Continued inactivity of the bowels and constipation would most deleteriously affect the nutrition and texture of the brain. It is impossible that the brain should have as good nourishment, or be made of as healthful material when there is habitual constipation.

Fifth cause of injury to the structure of the brain, and thereby a cause of insanity. Diseased lungs, and breathing of bad air. If the lungs are not fully expanded, the blood is not thoroughly purified, and a more or less diseased condition of the brain must necessarily ensue. The breathing of impure air tends to make tubercles and phthisis and an unhealthful condition of every tissue of the body, and will similarly affect the brain. The brain will necessarily be deteriorated in structure. I can but think this breathing of foul air is one of the most fruitful sources of injury to the texture of the brain and produces an unhealthful, diseased condition of that organ. By impure air the brain suffers as do other organs of the body. It is everywhere recognized that impure air produces in many persons scrofula. Lugol found insanity to be by no means rare among the parents of the scrofulous and tuberculous. Schroeder van der Kolk was of opinion that hereditary predisposition to phthisis might develop into or predipose to insanity; and, on the other hand, insanity predisposes to phthisis. We need not wonder then that authors so often notice the fact that insane patients are consumptive. Clouston says: "The frequent association of scrofula with idiocy and congenital imbecility is well known." Both may result from the same cause, as I have stated; breathing impure air will cause consumption, and tends to produce pathological changes in the brain.

Clouston also calls attention to the common occurrence of pulmonary phthisis as a cause of death among the insane, and says that it has been noted by those having charge of the older lunatic asylums.[1] Maudsley says: "Tubercle is often found in the bodies of the insane who have died without ever having been thought to have tubercle," adding: "The frequency of phthisis among the insane in asylums is great, but the inference that insanity directly predisposes the phthisis has been invalidated by proof."

Insanity does not predispose to phthisis, nor does phthisis predispose to insanity, but the same cause may produce them both. Maudsley asks: "Does insanity affect the progress of phthisis?" The seriousness of the existing conditions decides as to the progress of either disease.

Sixth: Another prolific cause of disease of the brain is unbalanced circulation. A whole world of meaning is in this. If we could only weigh or measure its import! The question of the fundamental principles of health and hygiene does not seem to have been especially dwelt upon in relation to diseases of the brain. We must come back to first principles. The brain is a physical organ of the body, and is controlled by the same laws of health as are other portions of our physical being. If the external skin, the feet, and extremities are cold, the blood will be driven from these parts and necessarily congest in other portions of the body. The blood is where it should not be, and frequently from this results more or less congestion of the brain. Congestion is the first condition of brain disease, and then may follow inflammation; and from the inflammation may in time be developed fibrous tissues and atrophy, or more serious conditions of disease, suppuration, abscess, or any abnormal formation. Dr. Benjamin Rush tells us that as one of the first symptoms "there is a sense of fulness, and sometimes pain in the head." This would be a direct result, and one of the first indications, of too much blood in the brain. Dr. Rush's theory is that "madness is seated primarily in the blood-vessels of the brain." Certainly in congestion and inflammation we always find the blood-vessels more or less changed. I have studied various diseased tissues under a power of 300, 400, 700, and 1,000. The blood-vessels always were changed according to the state and chronicity of the inflammation. All this may be the direct result of unbalanced circulation.

M. Parchappe remarks that "in acute insanity the prominent alterations are hyperæmic conditions." This would be directly produced by unbalanced circulation; and, if the hyperæmia continues, then we have, as Parcheppe terms it, "chronic insanity; the predominant alterations are atrophy of the convolutions and induration of the two substances."

If the congestion continues there would be first inflammation, then some other abnormal conditions may be produced, or the inflamed tissue may change to fibrous connective tissue, then we will have what is called chronic atrophy.

Any or all of these conditions may follow directly from unbalanced circulation in the system.

The external skin is an immense circulatory apparatus. A pin point cannot enter it without wounding or rupturing some blood-vessel. From some cause this circulation may become unbalanced; the blood is driven from the external skin; consequently too much in some other portions of the body, centering on the brain, may produce a fatal apoplexy or sudden death.[2] Or a slow congestion may gradually change the structure of some portion of the tissues of the brain, and thereby may result some brain disease and some form of insanity. Thus, I think, it can be proved that the

[1] Clouston terms it phthisical insanity. Maudsley in his work rightly objects to Dr. Clouston's term, "phthisical insanity," asking: "How then rightly style phthisical a clinical variety of insanity? The name phthisical cannot, I think, be accepted as convenient to designate a clinical group and succession of symptoms. There is no phthisical insanity anywhere." Maudsley does not seem to object to Clouston's other instances of this method of nomenclature for insanity when there is even more reason.

[2] Ellis says: "A very trifling alteration may produce the most important results, as in apoplexy the sudden extravasation of a small quantity of blood causes death."

external skin has more correlation with the brain, more power over it, more effect upon its condition, and more capability of producing insanity than the ovaries possible can have, with all their "menstruation," "ovulation," etc.

The first principles of the laws of health—good digestion, the breathing of pure air, a well-balanced circulation, maintained by suitable warmth and sufficient exercise—are essential to the health of the brain, and are really prophylactic and curative of insanity. It would be a beautiful problem to study the direct effect of regular exercise in the open air, not only in balancing the general circulation, but making a healthful circulation in the brain.

An eminent scholar who had written many books said, on his deathbed, that all his knowledge and learning were comprehended in the one simple direction: "Keep the feet warm, head cool, and the bowels open." Certainly to promote the health of the brain we must think of these first principles. Many diseased brains, if carefully attended to in time, may thereby be restored to health. Following this direction and the ordinary laws of health have much to do with preventing and curing insanity. The touching and beautiful words of the eminent and distinguished Dr. Benjamin Rush come in here. He says:[1] "I should lay down my pen, and bedew my paper with my tears, did I not know that the science of medicine has furnished a remedy for it. Blessed science! Which thus extends its friendly empire, not only over the evils of the body, but over those of the mind of the children of men."

ANALGESIA IN CHILDREN BY SPINAL INJECTION, WITH A REPORT OF A NEW METHOD OF STERILIZATION OF THE INJECTION FLUID.

By WILLIAM SEAMAN BAINBRIDGE, A.M., M.D.,

ATTENDING SURGEON, RANDALL'S ISLAND HOSPITAL; INSTRUCTOR IN OPERATIVE SURGERY, NEW YORK POST-GRADUATE HOSPITAL MEDICAL COLLEGE.

NOTWITHSTANDING the general employment of both chloroform and ether, over a long period of years, frequently there arises discussion as to the relative drawbacks in the employment of both of these anæsthetics. The advocates of each endeavor to prove the dangers attending the use of the other. While the profession believes strongly in the general usefulness of both of these remedies, the majority is convinced that there are cases in which either is liable to do harm. The presence of a marked kidney affection, acute inflammation of the bronchi, advanced pulmonary conditions, as well as pronounced arteriosclerosis, causes the surgeon no little apprehension concerning the use of any anæsthetic in such patients. While this does not apply so fully to children, still there are occasional cases when some substitute for ether or chloroform is greatly needed. Such an instance has occurred recently in my own practice, when a child had not been able to bear well the use of ordinary anæsthetics, and I resorted to spinal injection of cocaine with gratifying results. This has led me to a further study of the "Corning-Bier[2] method," especially in children in whom hitherto nothing has been done for those under eight years of age. The youngest cases recorded, so far as I know, were: by Murphy, a patient of eight years; by Bier, Lugueu, and Kinderdjy, who each reported one at the age of eleven; by Tuffier one at twelve, and by Seldowitsch one at thirteen. The following patients, which I report, range in age from two and a half to eleven years.

CASE I.—A. S——, male, aged nine years; strong healthy boy of moderate size but rather nervous temperament. Deformity of the left hip.

Cocaine analgesia, October 27, 1900. Place of puncture to the right between the fourth and fifth lumbar vertebræ. Amount of cocaine ℥ x. of a one-per-cent. solution. Injection complete at 11:39 A.M. Nausea and vomiting at 11:40 A.M., but none thereafter. Analgesia up to the level of the diaphragm at 1:42 A.M. The operation lasted twenty minutes, and consisted of a four-inch incision over the trochanter major, thoroughly exploring the hip joint. The patient complained of no pain and was quiet or talking to the nurse while the surgeons were at work. Before operation, temperature, 99.4° F.; pulse, 100; respiration, 28. One hour after operation, temperature, 99°; pulse, 92; respiration, 28. Analgesia disappeared completely at 3 P.M. During the afternoon the patient was fretful and complained of headache. Some milk was taken and retained during the afternoon. A small dose by mouth of acetanilid, sodium bicarbonate, and caffeine citrate gave a restful night.

October 28th: Slight afternoon elevation of temperature. The patient seems natural and has no headache. October 29th: No after-effects from the analgesia are left. December 1st: The patient is perfectly well.

CASE II.—J. J——, female, aged four years ten months; a healthy child of large size and very nervous temperament. Umbilical entero-epiplocele, size of a small hen's egg. (The parents were unwilling to use a mechanical support and insisted upon an operation.) The usual radical operation was done.

Cocaine analgesia, October 28, 1900. Place of puncture to the right between the fourth and fifth lumbar vertebræ. Amount of cocaine ℥ viii. of a one-per-cent. solution. Analgesia to the level of the diaphragm in two minutes. A return of the pain sense over the operative field in eighteen minutes necessitated a temporary discontinuance of the operation and a second injection. This was made to the left but between the same vertebræ as before, and consisted of ℥ vi. of the one-per-cent. solution. Analgesia to the level of the diaphragm in two minutes. Slight nausea and vomiting occurred directly after each injection. At times during the operation the patient was somewhat hysterical and cried as if in pain, but careful tests proved that the analgesia was complete. Before operation, temperature, 98.8°; pulse, 136; respiration, 30. One hour after operation, temperature, 99.2°; pulse, 140; respiration, 42. Analgesia disappeared completely in three hours from the second injection. The patient complained of headache, but had no nausea or vomiting. She retained a small quantity of milk during the evening.

October 30th: She has passed a comfortable night. No after-effects of the injection are present. December 1st: Convalescence has been uninterrupted.

CASE III.—R. K——, male, aged nine years; general condition only fair. Tuberculous caries of the ilium with inguinal sinus.

Cocaine analgesia, November 2, 1900. Place of puncture between the third and fourth lumbar vertebræ. Amount of cocaine ℥ xv. of a one-per-cent. solution. Analgesia to the level of the diaphragm in two and one-half minutes. In twelve and one-half minutes the loss of the pain sense had extended to the third costal cartilage in front, to the base of the spine of the scapula behind, and laterally over the axillæ and upper extremities to the middle of the forearm, excepting the deltoid regions. Slight nausea and vomiting occurred four and one-half minutes after the injection

[1] "Medical Inquiries and Observations upon the Diseases of the Mind," by Benjamin Rush, 1812, p. 95.

[2] Corning in his book on "Pain," published in 1894, reports cases of cocaine injection into the cauda equina for the relief of spinal irritation. This was years before Bier began his experiments.

was completed. Operation, consisting of an enlargement of the sinus and thorough curettage of the cavity with removal of some dead bone, was done without any pain or apparent nervousness. Before operation, temperature, 99°; pulse, 80; respiration, 24. One hour after operation, temperature, 98.4°; pulse, 80; respiration, 22. Four hours after operation, temperature, 101°; pulse, 124; respiration, 24. Analgesia disappeared completely two and one-half hours after injection. Headache was present for twenty-four hours but was controlled by acetanilid, caffeine citrate, and sodium bicarbonate. He vomited twice during the first night. There were no other after-effects to record.

December 1st: The patient is doing very well.

Case IV.—E. R——, female, aged two and one-half years; a strong, healthy child. Severe congenital talipes equino-varus with considerable genu varum of the right leg.

(1) Cocaine analgesia, November 2, 1900. Place of puncture to the right between the third and fourth lumbar vertebræ. Amount of cocaine ♏ vii. of a one-per-cent. solution. Involuntary stool in seven minutes and analgesia to the level of the diaphragm in twelve minutes from the completion of the injection. The operation lasted thirty minutes and consisted of an osteotomy of the right tibia, and an open tenotomy of all tendons behind the right internal malleolus. (Not wanting to overtax the child, I decided to let the left talipes remain until another time.) No vomiting or pain was experienced, and the condition of the patient after the operation was as good as before. A few moments after the injection the child's attention was absorbed in a new doll, which was presented to her on this occasion. Even the rough handling necessary in the forcing of the foot into the normal position did not cause any apparent discomfort. Before operation, temperature, 98.8°; pulse, 136; respiration, 30. One hour after operation, temperature, 99.4°; pulse, 132; respiration, 36. Analgesia disappeared about two hours after the injection. She passed a restless night.

November 4th: No after-effects are present.

(2) Eucaine analgesia, November 20, 1900. Place of puncture to the left between the third and fourth lumbar vertebræ. Amount of eucaine ♏ vii. of a one-per-cent. solution. Analgesia to the level of the umbilicus in ten minutes and gone in eighteen minutes. Second injection to the right between the third and fourth lumbar vertebræ. Amount of eucaine ♏ xv. of a one-per-cent. solution. Analgesia to the level of the diaphragm in five minutes. Not feeling sure of how long the eucaine would act, and being unwilling to use more of the drug at this time, I dressed the right leg and foot, thoroughly stretching the soft parts. No vomiting or pain appeared, but the patient seemed far more nervous than after the cocaine. Analgesia disappeared twenty minutes after the second injection. Before operation, temperature, 98.8°; pulse, 112; respiration, 26. Three hours after operation, temperature, 101.2°; pulse, 108; respiration, 24. Some headache was present for a few hours. She vomited once.

November 21st: No after-effects are noted.

(3) Cocaine analgesia, November 27, 1900. Place of puncture between the third and fourth lumbar vertebræ. Amount of cocaine ♏ x. of a one-per-cent. solution. Analgesia to the level of the diaphragm in seven minutes. The operation for the left talipes was the same as that done for the right, but no osteotomy was required. The patient was somewhat nervous and cried at times, but tests showed absence of pain during operation. Analgesia disappeared in a few hours, but the exact time was not taken. Before operation, temperature, 98.4°; pulse, 116; respiration, 26. One hour after operation, temperature, 99.6°; pulse, 50; respiration, 32. Some headache and restlessness were present the first night.

December 1st: She is doing well. No after-effects are noted.

Case V.—F. B——, male, aged nine years; epileptic. Congenital malformation of the glans and prepuce with slight hypospadias.

Cocaine analgesia, November 3, 1900. Place of puncture between the third and fourth lumbar vertebræ. Amount of cocaine ♏ xii. of a one-per-cent. solution. Analgesia to the level of the diaphragm in six minutes from the completion of the injection and at the same time slight nausea and vomiting occurred. The operation consisted of circumcision and meatotomy and lasted ten minutes. No pain or nervousness was noted. Before operation, temperature, 99°; pulse, 80; respiration, 24. One hour after operation, temperature, 99.6°; pulse, 130; respiration, 34. Analgesia was entirely gone two hours after operation, and seven hours afterward the patient had three slight epileptic convulsions, which were repeated a number of times during the night.

December 1st: Since the first sixteen hours after operation no epileptic convulsions have occurred, and the convalescence has been uninterrupted.

Case VI.—F. V——, male, aged seven years; in very poor general condition. Slight lumbar kyphosis and large psoas sinus with small inguinal opening.

Cocaine analgesia, November 3, 1900. Place of puncture to the right between the twelfth dorsal and first lumbar vertebræ, thus avoiding the site of the spinal curve. Amount of cocaine ♏ ix. of a one-per-cent. solution. In nine minutes after the injection analgesia was present over the entire body, except a space bounded behind by the posterior fontanelle, in front by the point of the chin, and laterally on each side by the angle of the jaw, the malar bone, the temporal ridge, and the parietal boss. Some nausea and vomiting occurred for a few minutes after the injection. During operation, which consisted of enlargement of the sinus, curettage of the bodies of the third and fourth lumbar vertebræ, besides a circumcision, the patient was free from pain and showed no sign of nervousness. He answered questions and showed full command of all his faculties. Analgesia disappeared in one and three-fourths hours. Before operation, temperature, 98.4°; pulse, 126; respiration, 34. One hour after operation, temperature, 100.6°; pulse, 108; respiration, 36. The headache was controlled by medication. He vomited twice during the night. The pulse was good.

November 4th: The child is restless at intervals and cries out. An ice cap is applied. Sodium bromide is given in small doses. The bowels are thoroughly opened.

November 5th: He seems stupid, and apparently is unable to express his desires in words. He does not move the right arm and hand, and the legs are drawn up. There is a slight elevation of temperature, with weak and rapid pulse.

November 6th: He continues stupid, does not talk, and there is very little movement of the right arm. The pulse demands stimulation. Strychnine and digitalin in small doses are given by the skin.

November 7th: He is improving.

November 8th: He is slowly gaining. There is slight movement of the right arm.

November 10th: He raised himself up in bed, and is brighter. The legs can be extended. He is moving the right arm.

November 12: Medication is discontinued. The pulse is strong.

November 15th: He is beginning to talk a little.

November 16th: He seems well, and speaks with no difficulty.

December 1st: He is in excellent condition, better than before operation.

Case VII.—A. F——, male, aged eleven years; in a fair general condition. Tuberculous ostitis of the head of the tibia with discharging sinus.

Eucaine analgesia, November 22, 1900. Place of puncture to the right between the third and fourth lumbar vertebræ. Amount of eucaine ℥ xxx. of a one-per-cent. solution. In four minutes after the injection a short period of nausea and vomiting occurred, and in seven minutes there was complete analgesia to the level of the diaphragm. The operation, consisting of the removal of dead bone and curettage of the sinus, was accomplished without pain. After twenty-five minutes the analgesia extended upward to the third rib in front, to the base of the spine of the scapula behind, and laterally on each side over the axilla, the inner aspect of the arm and forearm to within an inch of the styloid process of the ulna. Before operation, temperature, 98.2°; pulse, 84; respiration, 24. One hour after operation, temperature, 99°; pulse, 96; respiration, 28. Analgesia disappeared in about two and one-half hours, but the exact time was not taken. The pulse was weak after operation and the headache severe.

November 23d: Medicine is still necessary for the headache.

November 24th: He is feeling perfectly well.

December 1st: He is doing nicely. No after-effects are noted.

General Comments.—These cases have not been specially selected. The preparation of each was the same as usual before a general anæsthetic. The patient was placed in a sitting posture, well bent forward, and prevented from moving during the injection. After the skin over the site of puncture had been treated in the usual antiseptic way an ethyl-chloride spray was employed, rendering the introduction of the needle practically painless. I experienced no difficulty in introducing the needle. A point one-half inch to either side of the median line and midway between the spinous processes was taken, and the needle pushed forward, inward, and upward. Special effort was made to keep away from the central part of the spinal canal by a close relation of the needle point to the dura. The instrument used was of the simplest kind. A small-sized steel aspirating-needle with a short-bevelled pointed end, having a well-fitting hypodermic barrel, answered every purpose. As nearly as possible the same amount of cerebro-spinal fluid was allowed to escape as of the injection medium which was to be introduced. The injection was given slowly, usually taking one and one-half to two and one-half minutes. Often the first evidence that the cocaine was taking effect was some dilatation of the pupil or a slight nausea. During the operation a nurse known to the child stood close at hand, and the operative field and the instruments were screened from view. Anything which resembled a blindfolding excited and disturbed the patient. As far as possible general tests were made. There seemed to be no loss of motor power, and the ability to detect heat and cold and the muscular and tactile sense were retained. These are important points to remember, for too hot a solution or unduly rough handling may be thoughtlessly applied, causing the patient to become difficult to manage.

There have been many cases of failure reported which were attributed to the use of heat in the sterilization of the injection fluid. This fact led me early to experiment with other means. In all the above cases the following method has been employed with uniform success. While this simple way of sterilizing may be open to bacteriological objections, practical experiments, so far as I know, have proven it to be satisfactory. About a drachm of ether is poured over gr. v. of powdered cocaine or eucaine in a measuring-glass, which has been boiled, as well as the glass rod used to mix the ether thoroughly with the powder. The mixing-process is continued until all the ether has disappeared. Then one ounce of boiled filtered water is added. The solution is made fresh before each operation.

After-effects: In all cases any after-effects of an unpleasant nature were temporary. The urine on the day following the injection was examined in all cases for sugar and albumin. The result was uniformly negative. In only one case (No. VI.) were there any serious symptoms following the operation. Here was a high injection, with Pott's disease of the spine, in a patient in bad general condition. I was greatly aided in this work by Dr. W. E. Young and his assistants at the Randall's Island Hospital.

Cocaine versus eucaine: My cases so far have proved more satisfactory when cocaine has been employed. In one patient I had the opportunity of noticing the effects of both cocaine muriate and beta-eucaine hydrochlorate at different operations. The after-effects seemed no greater in one than in the other, and the analgesia was not so uniform or lasting when eucaine was employed. Most of the experimenters with this method of operating are using cocaine, but Lugueu and Kinderdjy are strong advocates of eucaine and are discarding the former in preference to the latter.

No final verdict for or against spinal injection, or what remedy is best to use, can be reached without further experimental evidence. The remote after-effects are yet to be determined.

(Since writing this paper I learn that Dr. A. Palmer Dudley reports in the Transactions of the New York Obstetrical Society, December, 1900, the use of chloroform in the sterilization of cocaine for spinal injection.)

34 Gramercy Park, New York.

The Value of Rest In Bed in the Treatment of Certain Digestive Disorders.—Albu draws attention to the frequency with which neurasthenia, anæmia, and malnutrition are associated and the great amount of injury to the system at large that may be produced by such a triad. The deficiency in nerve energy and the consequent imperfect innervation of the tissues lead to a general lack of muscular tone which finds expression in different ways according to the region of the body affected. In the abdomen the general relaxation has for its consequences visceroptosis and atony of the stomach and intestines with their attendant evils, and in proportion as the lack of proper nutrition increases the somatic weakness the debilitating events move in a vicious circle of greater and greater circumference and constantly involve more remote regions in the disease. Under such conditions the evident indications are rest and feeding. But to be properly effective the patient must completely change his previous faulty mode of life and be treated in a wholly alien environment. As a routine for such cases at least three weeks of absolute rest in bed, in some institution away from home, is to be advised, together with a full diet, for even though the state of the stomach may seem to contraindicate this over-feeding, in most cases it will relieve the symptoms more quickly than the most carefully adjusted but quantitatively insufficient régime. By these means bodily waste of all sorts, nerve and muscle, is reduced to a minimum and the depleted cells are enabled to regain their normal tone and vigor.—*Zeitschrift für Krankenpflege*, October, 1900.

The Elimination of the Inflamed, Gangrenous, or Perforated Vermiform Appendix from the General Peritoneal Cavity.—A. J. Ochsner urges a form of treatment which practically eliminates the appendix from the general peritoneal cavity. It consists of total abstention of food given through the mouth, the object being to secure absolute rest of the intestinal tract. The patient's strength is maintained by non-irritating, predigested, nutrient enemata every four to six hours, which should not exceed four ounces at a time. Water, preferably hot, can usually be given by the mouth, but if it causes peristalsis or nausea should be given by enema. This treatment will not protect the patient against a recurrence, nor against the troublesome digestive disturbances due to adhesions following appendicitis, but it will carry the patient safely over an acute attack, and will enable the surgeon to select a favorable time for operation. The author reports a number of cases.—*The Chicago Medical Recorder*, November, 1900.

Heart Disease or Epilepsy.—F. Savary Pearce reports several cases which tend to reinforce the fact of the possible existence of a great similarity between epileptoid phenomena—a petit mal—when the cardiac action is affected primarily, or when the so-called "heart failure" predominates in its symptomatology—and syncopal attacks independent of the epilepsy neurosis. As to early recognition of the significance of syncope, organic heart disease would be a sign in a difficult case, with a comatose mental state during the spell, that the syncope was of cardiac origin. Organic disease of the heart rarely causes convulsions. The less frequent and variable the apparent unconsciousness during an attack of syncope, the more likely the hysteroid nature. The presence of a slow, full, and irregular pulse, with or even without unconsciousness, makes more likely the epileptoid nature of the case. Leaky skin and cold extremities are more in favor of hystero-anæmic cases. The absence of pain in any case eliminates angina. Cyanosis is not common, except in the organic heart cases. A tendency to rigidity without convulsion is in favor of hysteria being the background of the clinical picture.—*Annals of Gynecology and Pediatry*, November, 1900.

Fibrinous Rhinitis.—J. M. Gill reports the case of a girl of five years who for three weeks had suffered from nasal obstruction and for a short period from fever. The right nostril was full of a substance looking like wet blotting-paper, but which proved to be a fibrinous cast of the inferior turbinate. The membrane re-formed several times, but finally disappeared. Examination showed almost a pure culture of a bacillus resembling in all respects that of diphtheria, and this view was confirmed by the result of inoculating guinea-pigs. One of the animals received along with the injection a dose of antitoxin, while another similarly inoculated did not. The animal receiving culture and antitoxin showed no signs of illness. The animal receiving only culture died in forty-eight hours.—*Australasian Medical Gazette*, October 20, 1900.

Saturnism among Stone-Cutters.—Ch. Fiessenger says that many of the cutters of precious stones in the Jura Mountains suffer from lead poisoning, due to the use of a leaden wheel in their work. The number of those affected has greatly diminished in the past fifteen years, owing to the progress made in a knowledge of hygiene and to decreasing use of the lead wheel. Saturnine gout is not known among these patients, probably because of their habits of sobriety, their moderate meat diet, and the high altitude at which they live. All the other symptoms of lead poisoning are present: hysteria, dyspepsia, neurasthenia, epilepsy, nephritis, anæmia, and paralysis. Tuberculosis is a frequent disease among lapidaries, but profound lead poisoning seems to confer immunity from this affection.—*Bulletin de l'Academie de Médecine*, October 30, 1900.

The Treatment of Insomnia due to Arteriosclerosis.—Friedeberg advises moderate outdoor exercise, which must be carefully regulated, however, and never include hill climbing owing to the palpitation likely to result. Cool baths are to be avoided, and even warm ones, taken at night, are prone to cause excitement in the aged. Sponging at bedtime is often beneficial, as are also warm drinks, but tea and coffee are to be interdicted. Care should be taken that the noonday nap does not exceed one-half hour in length. Narcotic drugs are to be avoided as much as possible, and, since the condition is due mainly to cerebral anæmia, attention should be given rather to the state of the circulation. Digitalis is nearly always useless for this purpose, but the nitrites give excellent results. Owing to its toxicity amyl nitrite should not be used, but both nitroglycerin and erythrol tetranitrite are often of signal service. The former may be given nightly in doses of gr. $\frac{1}{120}$ by mouth; should headache or nausea follow on awaking, it is an indication for omitting the drug for a week.—*Klinisch-therapeutische Wochenschrift*, October 21, 1900.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

ABUSE OF PROFESSIONAL POWER.

A RECENT occurrence in one of our large hospitals deserves more than a passing mention, for it has rarely been our duty to record a more unnecessary abuse of power on the part of a board of trustees.

The house physician of the institution referred to was a man of great promise. He had graduated from his medical college among the first ten in his class, and he had earned the esteem and affection of all who knew him. In the hospital, to which he was appointed after competitive examination, he was regarded as the equal in every way of any one who had ever held the position there of house physician. His term of service would have expired at the end of this month, and during his residence in the hospital he had never received a reprimand for neglect of duty or breach of discipline. A few weeks ago a member of the board of trustees of this institution, himself a physician, sent to the hospital, for admission to a medical ward, the servant of a lady of his acquaintance. The patient was suffering from the vomiting caused by chronic gastritis and recent pregnancy. Arriving at the hospital, accompanied by a physician from the country, she was taken to the accident-room, placed under the care of a very experienced trained nurse, and the usual and ordinary notice was sent to the house physician that a patient awaited his examination. The house physician's occupation at the time was such that he failed to visit this serious and distressing case until perhaps thirty minutes (but not more) had elapsed. The patient was then admitted to the public ward, her needs were attended to, and at the end of one week the symptoms of which she had complained were entirely relieved.

Complaint was made to the medical member of the board of trustees who had recommended the patient for admission to the hospital that she had been unduly kept waiting before being seen by the house physician. This trustee, himself a medical man noted for his delicate sympathy with charity patients and with his professional brothers when they are in trouble, would, of course, under other circumstances, have been satisfied with warning the young man that he must be more prompt in his attendance on patients waiting for examination. But he himself had recommended the patient, and the patient was a servant of one of his well-to-do lady acquaintances. A few days later a very severe reprimand was administered to the house physician by the executive committee of the hospital and about two weeks ago the young man was summoned before the full board of trustees.

Very severe remarks were made to him, and he was informed, among other things, that the professional men connected with the hospital were to understand that they were its servants. The medical member added his words of abuse.

The result of the deliberations of the elderly men who manage this important charitable institution was that the house physician was suspended for the remainder of his term of service, and requested to leave the hospital at the earliest possible moment. For an entirely harmless and innocent breach of discipline a professional man of unblemished character and of fine education has been dismissed from his hospital service as though he had committed a crime.

In addition to the grave injury done to the individual, the harm done by such action as this spreads very widely. It breeds dislike and disloyalty at a rapid rate among the young men who would naturally be the staunchest supporters of the institution with which they have associated themselves, and whose friendship it is very desirable for the institution to cultivate. It serves as a loud warning to those seeking hospital positions to go where they will be treated with ordinary kindness and courtesy; and it leads the public entirely to distrust the capacity of a management which is capable of so grossly mismanaging.

Discipline must be maintained in all institutions, but the Chinese method of beheading for trivial offences will never find favor in this country.

ANGINA PECTORIS.

ANGINA pectoris may be defined as a symptom complex dependent upon disturbance in the functional activity of the heart muscle, resulting either from organic causes, such as disease of the coronary arteries or of the myocardium itself, or from toxic influences, such as may arise from excessive indulgence in alcohol, tea, or coffee. It has been the custom to designate cases of the first kind "true" and those of the second kind "false," but it would seem better to employ instead the qualifications "severe" and "mild" respectively. Derangement of function must always be referred to alteration in structure or in nutrition, and the degree of the former will necessarily vary with the character and the intensity of the latter. Normal function must be looked upon as the resultant of metabolic activity, whose derangement will be attended with altered nutrition, which if profound or long continued or frequently repeated, in consequence of either intrinsic or extrinsic influences, may lead to structural alteration. In accordance with the foregoing considerations, angina pectoris would not necessarily be a disorder of the degenerative period of life, and not invariably fatal. but the prognosis would vary with the nature of the underlying condition. In reporting briefly five cases of angina pectoris, three of which terminated fatally, and in two of which recovery en-

sued, Salomon (*Berliner klinische Wochenschrift*, 1900, No. 36, p. 275) points out that, inasmuch as the etiological factors are so varied, it is not to be expected that the lesions present should always be the same. Thus, among the conditions assigned as causative influences are syphilis, alcoholism, long-continued mental and physical strain, frequently repeated and long-continued depressing emotional states, diabetes, gout, acute infectious diseases, excessive indulgence in tobacco, tea and coffee, over-eating with insufficient exercise, and lead poisoning. In any event the treatment is much the same. In the paroxysm inhalations of ether, chloroform, or amyl nitrite, hypodermic injections of morphine, or the administration of nitroglycerin may be practised, while in the intervals the diet and the mode of life generally will require to be regulated, and iodide should be administered.

THE SOUTH AFRICAN MILITARY HOSPITALS COMMISSION.

This commission has just completed the taking of evidence, and until it makes its report it would be impossible to say what its finding may be. However, to judge from the statements tendered by witnesses, the summing up cannot be altogether favorable to the medical arrangements of the British army. In fact, it is admitted by every unprejudiced person who has seen the conditions of the South African hospitals that the provision was insufficient in many respects. Almost all the British medical journals at the commencement of the war drew attention to the inadequacy of the army medical corps, and some indeed went so far as to predict a complete breakdown of that branch of the service if the campaign should be a long one. These presages of evil were not fulfilled, and, until enteric fever broke out and spread on a large scale, the army surgeons, supplemented by a number drawn from civil life, showed themselves well able to cope with the difficulties of the situation. Even then it is claimed that the blame for the partial breakdown rests on the war office and military authorities rather than on the medical department. One fact stands out prominently, and of this the whole British nation seems to be thoroughly convinced—that the army medical corps must be reformed, root and branch. There are some points of similarity between the conduct of the South African war as regards the medical service and our war with Spain. In both campaigns the supply of army surgeons was not equal to the demand, and in both the gaps had to be filled by non-military medical practitioners. Again there would appear, from all accounts, to have been a certain parallel between the manner in which medical supplies failed to reach the places where they were needed. With regard to nursing, the opinion of the most distinguished British military authorities has undergone a considerable change during the progress of the South African war. A writer of note in the *Edinburgh Review* has this to say on the subject: "Although the traditions of the army medical corps are opposed to female nursing, assigning nearly nine times as many male as female nurses to a general hospital, suffice it to say that at the present time almost all men from Lord Wolseley and Lord Roberts downwards, recognize its desirability, more especially in fever cases, which are the common scourge of young soldiers." And in another part of the same article the writer says: "The army has hitherto neglected the question of female nursing. In the early stages of the war nurses were not only deficient, but offers of trained nurses were actually declined. As, however, the war proceeded, orderlies became scarce, and as Lord Roberts insisted on female nursing, and as the usefulness of such assistance became apparent to all, more particularly at the base hospitals and in the fever hospitals, the number of nurses was increased. Clearly the experience of the war is in favor of female nursing to be utilized to a far greater extent than hitherto, having this further advantage of releasing men for work at the immediate front. This in turn will necessitate that organization of a female nursing service which has hitherto been neglected." In the Spanish-American war the services of female nurses were dispensed with as much as possible, and our medical and military authorities, like the British, declined to engage female nurses. In an editorial in the Medical Record some few months ago the question of female nursing was briefly touched upon, and the opinion was expressed that when feasible well-trained female nurses should be employed in preference to men nurses, especially in base hospitals. It is therefore some gratification that our views should be borne out by the experience of a man so versed in all pertaining to modern warfare as Lord Roberts. The report of the South African military hospitals commission must be instructive, and will be awaited with much interest by army and civil medical men in this country.

THE SURGICAL TREATMENT OF PRIMARY RENAL TUBERCULOSIS.

Although it is known that tuberculosis in any organ may undergo spontaneous recovery, and while the results of intelligent medicinal and hygienic treatment are at times entirely satisfactory, the outcome cannot be safely predicated in any given case. For this reason, and in view of the relative malignancy of the disease, the adoption of surgical measures for its removal would seem to be indicated whenever practicable. The decision will often be a most delicate one, in consequence of the difficulty at times encountered in diagnosis, the uncertainty of result, and the possibility of extensive involvement. This general statement is applicable with especial force to tuberculosis of the kidney, in which often the disease is primary and circumscribed. If surgical intervention has been decided upon, the question as to the character of the operation will arise. For the purpose of reaching a decision in these matters, O. G. Ramsay (*Annals of Surgery*, October, 1900, p. 461) has collected from various sources three hundred and four cases of renal tuberculosis in which some form of operative treatment was employed, and from an analysis of which he believes that renal

tuberculosis may be considered a semi-malignant form of inflammation, and that for this reason surgical treatment of some sort is always indicated. This treatment will have a palliative or a curative end in view, in accordance with the condition of the patient and the duration and extent of the disease. Nephrotomy in cases of renal tuberculosis is to be considered a palliative operation, and, practised from this point of view for the immediate relief of dangerous symptoms and as not precluding subsequent nephrectomy, nephrotomy with drainage of the abscess cavity is a most valuable procedure. Resection of the diseased portion of the kidney is contraindicated, because of the danger of leaving a tuberculous focus in the remaining portion. Nephrectomy, or nephro-ureterectomy, is indicated in all suitable cases, in 55.5 per cent. of which it should effect a permanent cure. The contraindications to nephrectomy are tuberculous or other disease of the second kidney, or the presence of tuberculosis in other organs. Tuberculosis of the bladder is not to be considered a contraindication to nephrectomy, as it will probably undergo subsequent cure. A small tuberculous focus in the lung, if the patient is otherwise in good condition, may sometimes not be considered a contraindication. In doubtful cases, when it is questionable whether the patient can stand an immediate nephrectomy, it is better to perform nephrotomy, to be followed later by nephrectomy. The clamp method of controlling the pedicle is contraindicated on account of the danger of hemorrhage on removal of the clamp. It is safest to remove the ureter with the kidney, as otherwise a permanent fistula may remain. A certain proportion of such fistulæ will finally disappear, either after the removal of a deep suture or in consequence of the slow disappearance of the tuberculous disease of the ureter, which under such circumstances is gradually converted into a fibrous cord. A steadily increasing number of cases of permanent recovery may be expected as our means of diagnosis improve, and as our surgical technique is carried out more carefully and scientifically.

News of the Week.

Pathological Society of Philadelphia.—At a stated meeting held November 22d Drs. George E. de Schweinitz and Edward A. Shumway reported "Two Cases of Glioma of the Retina," and discussed current views as to the histology. Dr. Charles Wardell Stiles, of the bureau of animal industry of the department of agriculture, presented by invitation a communication entitled "Parasitic Hæmoptysis," an affection that has been observed in considerable numbers of human beings in China and Japan and of animals in the United States. The disorder is dependent upon the presence of the Paragonimus Westermannii, a fluke, which most often finds lodgment in the lungs and sometimes in other viscera also. The parasite is derived from snails, which act as the intermediate hosts, and are ingested with the water. Dr. Stiles demonstrated both the parasite and the ova, and he pointed out the possibility of the importation of the disease with a return of American soldiers who had seen service in China and the Philippines. Dr. F. Savary Pearce presented the specimen from, and related the history of, "A Case of Hemorrhage into the Crus Cerebri and Pons Varolii." Dr. Joseph McFarland exhibited a heart containing a mural thrombus in the left ventricle and a globular thrombus in the left auricle, and also a heart presenting extreme aortic obstruction with enormous hypertrophy of the myocardium.

Memorial to Physician.—It is proposed by the people of Burlington, N. J., to secure by popular subscription funds for the purchase of the old colonial mansion in which the late Dr. Frederick Ganutt lived, and its conversion into a memorial hospital.

Faith Curists Held for Murder.—Two men, a "healer" and one of his followers, are held in Victoria, B. C., for murder on account of the death of the son of one of the accused from diphtheria. The only treatment the child received consisted in the incantations of the healer, who was one of Dowie's "Zionites."

The Army Hospitals Scandal.—The testimony in regard to the charges brought by Mr. Burdett-Coutts against the management of the British army hospitals in South Africa is now all in. The last witness examined by the hospital commission was Mrs. Richard Chamberlain, who had been before the commission once before. At the first examination she said that "the army surgeons were, with very few exceptions, a low class of men. Those in South Africa neglected their patients. Six cases of drunkenness among army doctors came under my observation. After these people had come into contact with the police they were sent home in charge of invalids." At her final examination she repeated her former testimony and branched out into vituperation of the army surgeons, the commissioners, and everybody else who did not agree with her. She said that she considered herself more capable of conducting hospitals than medical officers, and she insulted the president, Justice Romer, telling him that he acted more like counsel with a brief from the army doctors than an inquisitor.

War against Malaria in Italy.—We read in the *Medical Press and Circular* that an attempt on an enormous scale to stamp out malaria is about to be initiated in Italy. The plan, which has been elaborated by Professor Grassi, is to begin operations on the coast south of Naples. In a region covering some thirty thousand square miles every house is to be provided with wire screens to the doors and windows (a possibly feasible though somewhat expensive measure), and all the inmates of these screened houses are to be kept indoors between sunset and sunrise (but how they are to be kept inside, unless there are guards outside to watch them, is not made clear). Those who, in spite of these precautions, are attacked by malaria will be isolated in mosquito-proof quarters and will be supplied with quinine free of cost. It is possible, of course, that Professor Grassi will succeed, but it is

hardly probable. An attempt to exterminate all the mosquitos in the district would be less expensive and more likely to succeed.

The Smallpox Outbreak in this city is fairly well under control, though new cases are found from time to time.

The Plague in San Francisco.—It is reported that another death from the plague has occurred in San Francisco. The quarantine against the city is still maintained by the Texas authorities, and it is believed that Louisiana and other of the Southern States will also declare a quarantine against it.

Faith-Curists Sentenced to Imprisonment.—Two faith-curists, who pleaded guilty to a charge of manslaughter in connection with the death of a child confided to their care, were sentenced to an imprisonment of three months in the county prison by Judge Audenried at Philadelphia on December 6th.

An Epileptic Colony in Illinois.—The board of commissioners of public charities has reported to Governor Tanner on the question of a site for an Illinois colony of epileptics, favoring a location in Ogle County. The legislature will be asked to appropriate $350,000 for the purchase of the grounds and the erection of the buildings.

The Western Surgical and Gynæcological Association.—The next annual meeting of this association will be held at Minneapolis, Minn., December 27 and 28, 1900. The following are the officers for this meeting: *President*, O. B. Campbell, St. Joseph, Mo.; *First Vice-President*, A. C. Bernays, St. Louis, Mo.; *Second Vice-President*, J. R. Hollingsworth, Rock Island, Ill.; *Secretary and Treasurer*, George H. Simmons, Chicago, Ill.

College of Physicians of Philadelphia.—At a stated meeting held December 5th, Dr. Joseph Leidy presented "Some Replicas of Surgical Instruments Found in the Ruins of Pompeii." Dr. Charles P. Noble read a paper entitled "The Making of a New Urethra After its Complete Destruction," reporting an illustrative case. Dr. A. E. Woldert read by invitation a paper entitled "Cultivation of the Æstivo-Autumnal Malarial Parasite in the Mosquito—Anopheles quadrimaculata (claviger)—with Presentation of Original Specimen."

The Pan-American Medical Congress at Havana has been postponed until February 4–9, 1901, because of the unusual prevalence of yellow fever in that city. This will be a more convenient season for American physicians to visit Cuba, and there will probably be a larger attendance of them at that time than there would have been in Christmas week. Perhaps, also, by that time certain irate Cuban physicians, whose names do not appear on any of the committee lists and who have been abusing General Wood and other Americans in *El Progreso Medico*, will have cooled down a little. They are now enraged because General Wood did not sanction a public appropriation to pay the expenses of the congress, but said very properly that they should be met by private subscriptions.

The Study of Tropical Medicine in France.—The Faculté de Médecine of Paris has decided to establish a school for the study of tropical diseases, with special chairs of bacteriology and parasitology. A public appeal will be made for funds to carry on the school.

The Water Supply of Cheyenne, Wyoming, has been examined and found to be badly contaminated—so states the *Leader* of that city. The immediate occasion of the examination was the occurrence of an unusually large number of cases of typhoid fever, over fifty deaths having taken place in the past four weeks.

A Congress for the Study of Cancer will be held in Chicago on the first Tuesday in May, 1901. The following are the subjects announced for the set discussions: (1) What are the most successful methods of treatment? (2) What are the values of antitoxins? (3) What is the cause or the causes of cancer? (4) Why is cancer on the increase? (5) Classification of the varieties of cancer and the most important advances made in the study of their pathology.

Philadelphia Hospital.—The fourteenth annual reunion and dinner of the Association of Ex-Resident and Resident Physicians of the Philadelphia Hospital was held on December 4th, with an attendance of nearly sixty. Dr. E. L. Duer presided, and Dr. J. B. Walker acted as chairman of the executive committee and as toastmaster. Toasts were responded to as follows: "Our Rulers," Dr. H. C. Wood; "Our Chiefs," Dr. W. Frank Hachules; "Our Nurses," Dr. D. J. McCarthy; "Our Residents," Dr. Edward Robinson; "Our Patients," Dr. Augustus A. Eshner. The following officers were elected for the ensuing year: *President*, Dr. E. L. Duer; *Vice-Presidents*, Dr. H. C. Wood and Dr. J. K. Lineaweaver; *Secretary*, Dr. E. R. Stone; *Chairman of the Executive Committee*, Dr. R. G. Curtin.

Precautions against Tuberculosis in Germany.—The German department of the interior has issued instructions for compulsory precautions against the spread of tuberculosis in the empire. The orders provide that physicians having patients with pulmonary or laryngeal tuberculosis shall give written notice to the police as soon as the diagnosis has been made; that immediately after the death of a person from tuberculosis the deceased's room and effects must be thoroughly disinfected; that professional women who lay out the dead must report at once in writing to the police authorities whether the disease was of the lungs or larynx, and that keepers of hotels, lodging-houses, asylums, or other public institutions shall report immediately the appearance of the disease in the establishments under their control. Non-compliance with the regulations is subject to a fine of 150 marks or six weeks' imprisonment.

Arseniated Beer in England.—Referring to the Manchester beer-poisoning cases, the *Lancet* of December 8th says that definite steps are being taken to stop the sale in England of beer containing poisonous impurities. A specimen of invert sugar (a variety of sugar consisting of a mixture of dextrose and levulose,

found naturally in fruits and produced artificially by the inversion of cane sugar) used in brewing was examined in the *Lancet* laboratory, and was found to contain three grains of arsenious acid per pound. Hence a glass of beer might contain one-fifth of a grain of arsenic. An examination into the form in which arsenic existed in this sugar showed that it was mostly in that of arsenious acid in small quantities. Arsenic acid was also detected. The *Lancet* appeals to the government to define beer as a liquid brewed exclusively from barley, malt, and hops, so that beer made from substitutes for these ingredients will have to be called by another name. It says that arsenic was found in beers manufactured from glucose in other countries years ago.

Conviction of the Proprietors of a Chicago Diploma Mill.—A verdict of guilty was rendered on December 8th against the two proprietors of the "Metropolitan Medical College" of Chicago, who had been arrested for using the mails to defraud.

Typhoid Fever at Sing Sing.—On last Saturday there were seventeen cases of typhoid fever in the Sing Sing prison hospital, and several cases have developed since that time.

Appointments.—Dr. Joseph Collins has been appointed consulting neurologist to the Hospital for the Ruptured and Crippled of this city. Dr. Henry Heiman has been appointed adjunct visiting physician to the children's service in the Mt. Sinai Hospital.

Physician, Convict, and Turnkey.—A physician in a Colorado town is serving a sentence in the county jail for manslaughter. He is a "trusty" and is allowed to go at will through the town, where he enjoys a considerable practice. At the same time he is acting sheriff, the county sheriff having gone away for a time, leaving to him the care of the keys of the jail.

Graduation of Colored Nurses.—Six colored women, graduates of the Colored Home and Hospital Training-School for Nurses, received their diplomas one evening last week in the lecture hall of the Academy of Medicine. This is the first time that there has been graduated a class of colored nurses in any northern city. There are in the South two schools for the education of negro nurses, but they are of comparatively recent foundation. Dr. Stephen Smith delivered the address to the graduates.

New Buildings of the New York Hospital.—The new buildings of the New York Hospital were opened last week. They are located just west of the older buildings on West Fifteenth Street, and consist of a ten-story building for private patients, a four-story dormitory for the hospital employees, and the governor's building, which is in the centre of the group. The first floor of the private patients' building is for administrative purposes. The physicians have their quarters on the second floor, the operating-rooms are on the top floor, and the rest of the building is for the patients. There are many single rooms and some suites of several rooms. Each of the two operating-rooms on the top floor has its own separate suite of etherizing, sterlizing, and wash rooms, and each has a separate ventilating-plant. In the rear of the building for private patients there is an isolating-department.

Pink Eye is reported to be epidemic in Chicago, the extremely dusty condition of the windy city being set down as the cause.

Vaccination in the Yukon.—It is reported that there were thirty cases of smallpox at Dawson City the first of November. The Yukon council has passed an ordinance requiring all persons in Yukon territory to be vaccinated. Fifteen thousand persons are affected by this order.

Typhoid Fever in Washington.—In presenting a report of a committee of physicians upon the filtration of the water supplied to the city of Washington, in the senate on Friday of last week, Dr. Gallinger adverted to the alarming prevalence of typhoid fever in the District of Columbia. He declared that the death rate in this city from that disease was seven or eight times as great as in European cities of the same class. The wells of the District had been closed, but the ravages of the fever had rather increased than diminished.

Medical Colleges United in St. Louis.—The announcement is made that the Marion-Sims College of Medicine and the Beaumont Hospital Medical College of St. Louis have agreed to a consolidation, which will become effective May 1, 1910. The terms of the consolidation contemplate a utilization of the entire teaching-force of the two institutions and a union of their clinical facilities and laboratory equipments. The old Beaumont building at Jefferson Avenue and Pine Street will be sold, and the Marion-Sims building at Grand Avenue and Caroline Street, with new additions already projected, will be used by the new Marion-Sims-Beaumont College of Medicine.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the navy for the week ending December 8, 1900. November 20th.—Passed Assistant Surgeon R. B. Blakeman ordered to be examined December 10th, at Washington, D. C., for retirement, and thence home to wait orders. Passed Assistant Surgeon A. W. Dunbar ordered to the *Vermont* for duty with the crew of the *Wisconsin* revoked; ordered to duty at naval hospital, Mare Island, December 14th. Assistant Surgeon W. M. Carton ordered to the Washington navy yard, December 5th. December 5th.—Surgeon C. Biddle ordered to the naval hospital, Norfolk, Va., for temporary duty. December 7th.—Assistant Surgeon E. J. Grow detached from the *Monadnock* and ordered to the *Culgoa*. Pharmacist J. Cowan detached from the *Monadnock* and ordered to the *Culgoa*, and to additional duty at the Cavite naval station.

Obituary Notes.—Dr. K. Frederick Kebler, formerly of Cincinnati, died at Somerville, Mass., on November 23d. He was born in Cincinnati in 1850 and was graduated from the Ohio Medical College in 1875. He early gave promise of a brilliant career as a pa-

thologist, but became mentally afflicted and spent the last years of his life in a sanatorium.

Dr. George Banks, of Huntington, L. I., died on December 4th at the age of seventy-five years. He was a graduate of the College of Physicians and Surgeons of New York in the class of 1860.

The Rev. William Everett, rector of the Roman Catholic Church of the Nativity in this city, died on December 7th at the age of eighty-six years. He was born in Albany and was graduated in medicine in this city in 1834. He practised for a few years and then studied divinity, being ordained a priest in 1853.

Dr. Edward Smith died at his home in this city on December 10th at the age of seventy-one years. He was born in Stonington, Conn., and was graduated in medicine from the University of Pennsylvania in 1852. For a time he served as assistant physician in the State Lunatic Asylum at Worcester, Mass. In 1856 he was appointed an assistant physician in the Pennsylvania Hospital for the Insane at Philadelphia. In 1862 he resigned to become one of the surgeons in the United States Military Hospital at Philadelphia. After the war he took up private practice in Philadelphia. In 1878 he moved to New York, where he had since lived.

Dr. Joseph T. Shoemaker died at Philadelphia on December 6th at the age of sixty-two years. He was graduated from the medical department of the University of Pennsylvania in 1861, and during the War of the Rebellion served as surgeon in the Eighty-eighth Pennsylvania Volunteers.

Dr. Frederick W. Pleibel died at Philadelphia on December 6th at the age of sixty-six years. He was graduated from the medical department of the University of Pennsylvania in 1857.

Progress of Medical Science.

New York Medical Journal, December 8, 1900.

Notes on the Hospital Scarlet-Fever Service in New York City from 1893 to 1899 Inclusive.—By W. L. Somerset. This is a study of 2,627 cases treated during the period mentioned in the Riverside and Willard Parker hospitals. The mortality rate was nine per cent. Concerning treatment the author writes as follows: For the general welfare of the patients and for the avoidance of complications, rest in bed, and fluid or semi-fluid diet were insisted on for three weeks. For the scarlet fever itself, streptococcus antitoxin was tried for a short time, the immediate object being to test its effect on scarlatinal throats. The results obtained, however, did not seem to justify the continuance of its use. Frequent sponging with weak solutions of carbolic acid or bicarbonate of sodium was utilized for itching, painful tension, or other irritable conditions of the skin. The temperature was usually treated according to its effects on the patient. In cases in which the distress was out of proportion to the rise of temperature, the relief afforded to the extreme restlessness, insomnia, or even delirium, by means of baths, could be very much augmented by the use of sedative drugs. Among the various remedies used, a phenobromide combination was most effective. It acted well as both a sedative and an antipyretic, and could be given to children in much larger and more effective doses without causing depression than any of the other sedatives. With temperatures unusually high or unusually persistent, baths and packs were largely used. A graduated bath was often given, beginning at the temperature of the patient, and reducing the temperature, in from ten to fifteen minutes, 20, 30, or even 40° F. There is no particular danger of the patient's taking cold, and there are very few, if any, contraindications to the reduction of a temperature of 106° F. If the temperature of the bath must be very low—say 65° F.—or even that of an ice pack, heat applied during the bath or pack to the arms and legs by wrapping them with hot blankets, is an excellent aid in avoiding depression. Too much stress cannot be laid on the necessity for careful and skilful attention to the ears: early diagnosis, anticipation of rupture of the membrana tympani by early operative intervention, or proper enlargement of the opening when rupture has occurred, both to promote freer discharge and to secure better drainage; scrupulous and persistent cleanliness in all cases with discharging ears, are all of the highest importance. Equally important is attention to every detail affecting the best interests of the kidneys.

Mastoid Abscess.—R. A. Wright comments on the case reported by Harrigan in the issue of November 10th, and states that the selective time for successful operation in mastoid disease is early after diagnosis; just so soon as ordinary antiphlogistic measures (Leiter's coil, leeching, etc.) fail to check the inflammation. There is no reason to wait until pain and suffering have so reduced the patient's strength that operative procedure means almost certain death. He concludes by saying that early recognition of the site of the perforation, with adequate treatment, usually prevents mastoid complications in disease affecting primarily Prussak's space, with perforation of Shrapnell's membrane.

A Plea for General Anæsthesia in the Treatment of Mammary Abscess.—F. H. Field condemns the superficial incisions so often made in the treatment of this condition, for we do not know in what directions or how deeply the pus may have burrowed, and it is often necessary to resort finally to a late and extensive operation when a simple one done earlier would, if thoroughly performed, have been sufficient. He prefers chloroform anæsthesia. Healing may be confidently predicted in from seven to ten days. The use of linseed poultices under the circumstances he strongly condemns.

The Operation for Hypospadias with the Demonstration of Three Cases Successfully Treated by Forward Dislocation of the Urethra.—By Carl Beck.

Medical News, December 8, 1900.

A Modification of the Mosquito Theory.—Charles R. Grandy declares that he believes in the potency of the Anopheles to propagate the malarial organism, but he also believes that they can and do obtain organisms from other sources than direct from the human blood. He thinks it probable that when feeding on other things than human blood (which seems to be more of a delicacy than a staple article of diet with the mosquito tribe) it also injects the parasites into whatever it is eating. Other uninfected Anopheles may take in the parasites directly from this food or water; or the plasmodia, in the form in which they are found in the parotid glands, may be able to live in water or damp soil as other sporozoa do, and later on they may be taken up by other Anopheles and be inoculated by them into man. It is also possible that the plasmodia may pass into the water from the bodies of the Anopheles which have died in the water after depositing their eggs, and may be taken up in feeding by other mosquitos. Whenever malarial fever regularly appears there is found the Anopheles. Anopheles breeds only in pools and not in tubs; it is the country mosquito in contradistinction to Culex, which is found in both towns and country. They feed at night. They are most numerous at the time of the heavy dews in August and September. Their larvæ feed on algæ, hence the theory that stagnant water causes malaria. The two objections to this modified theory are: (1) The malarial organisms have never been cultured artificially; but no other parasitic protozoon has been thus cultured. (2) They have never been found free in nature; but the tiny thread-like organisms are so minute that they could easily escape observation when looked for in water. The writer believes that although there is as yet no positive proof of this theory, still it comes nearer fulfilling all conditions and answering all objections than any other which he has seen.

A Study of Drainage.—A. M. Pond states that drainage was first used to remove the pus which was the inevitable concomitant of surgery before the present era of asepsis and antisepsis. Drainage was then considered, and justly, a necessity, since without it absorption of poisonous material was inevitable. Latterly we have drained to prevent pus formation, a process, the writer believes, essentially unscientific. In certain of the septic and infective cases we must continue to drain, because we know pus has formed, although many septic cases can be made sterile and the wound closed without drainage. In abdominal surgery there is another method of combating infection,

viz., purgation. By diluting infection we promote absorption, *e.g.*, by the use of salt solution. Many unfortunate sequelæ follow in the wake of abdominal drainage. Hernia is common. No other cause of ileus is so common, and removal of the gauze drain when the tender granulations have grown through the drain's meshes, and are torn, causes great pain and sometimes serious relapse. Blood serum plays an important part in the repair of wounds, chemotaxis bears an important relation to pus formation, and in sterile cases drainage is not only unnecessary but positively detrimental. Consequently the writer concludes that drainage should be restricted to those cases which all the means at disposal fail to render aseptic and non-infective.

An Improved Technic in Amputation of Large Rectal Prolapse.—George Ryerson Fowler describes this method in which the patient assumes the combined lithotomy and Trendelenburg position in order to prevent the descent of the small intestines during the operation, thus providing against injury to these during the suturing. In the case which he reports cocaine anæsthesia was used, thus enabling the patient to extrude the prolapse fully, so that no traction was necessary. A cuff at the muco-cutaneous margin was turned back for the purpose of preserving the normal conditions at the rectal outlet, and at the same time permitting the removal of all the relaxed and overstretched mucous and submucous structures at this point. The cuff also offers a covering for the sutured edges of the stump of the prolapse and diminishes opportunities for subsequent infection. Another advantage of this particular method described consists in the step-by-step application of, first, a suture, and then an extension of the incision through both cylinders to correspond with the sutured area, in this manner avoiding exposure of the peritoneal cavity to infection.

Chloralamid.—By S. V. Clevenger.

Journal of the American Medical Ass'n, Dec. 8, 1900.

Immature Cataract and its Treatment.—G. E. De Schweinitz concludes that: (1) Certain lenticular opacities, most often situated in the naso-inferior quadrant of the lens, occasionally are practically stationary and may be designated "non-progressive." They do not handicap the patient's ocular abilities, and may with propriety be separated from the class to which the name incipient cataract is ordinarily given. (2) Certain lenticular opacities undoubtedly depend, as Risley and others have shown, on what may be designated "disturbances of the choroid," as apart from active and actual choroiditis; and their progress is sometimes apparently checked by measures—optical, local, and general medicinal—which restore the choroid coat to normality. Such measures do not, however, remove from the lens the opacities which have already formed when the patient comes under treatment. (3) Certain lenticular opacities which appear in association with diabetes mellitus, nephritis, lithæmia, and arteriosclerosis, particularly the last two diseases, are sometimes apparently retarded, like those in No. 2, by measures which are suited to the patient's general condition in connection with local and optical therapeutics, but these measures never dissipate the lens lesions already present. (4) The extraction of unripe cataracts is preferable to any of the ordinary operations for ripening cataract. (5) There is no evidence that electricity has the slightest influence in checking the rate of progress of incipient cataracts, or in dissipating the opacities which have formed. (6) There is very insufficient evidence, if any, that massage of the eyeball favorably modifies the rate of development of cataract. (7) There are no "specific remedies" for the treatment of cataract, and there is no reliable evidence that drugs exist which cause the absorption of partially or fully formed cataracts. (8) All lenticular opacities, unless the "non-progressive" group, should iudicate a thorough investigation of the patient from the general as well as the ocular standpoint and the employment of remedies according to the findings.

Subtrochanteric Amputation for Diffuse Skin Carcinoma.—This case is reported by Emanuel J. Senn. The patient, a man aged twenty-three years, was struck on the inner side of the thigh when he was nine years of age. After the injury there was a denuded surface on the inner aspect of the knee about the size of the palm of the hand. It was skin-grafted. An area the size of a dime never healed. Later, when the patient was twenty-two years of age, an ulcer formed above this spot and grew rapidly. Almost the entire circumference of the thigh was affected and there was a chain of enlarged glands in the groin. At this time he was admitted to the hospital and given a thorough course of supportive treatment. After he had gained in strength, a subtrochanteric amputation was performed in the orthodox manner. The wound healed by primary intention. He refused an operation for removal of the lymphatic glands. Microscopical examination showed this diseased tissue to be carcinomatous. The patient has been seen lately and is in excellent health, having gained over thirty pounds. The lymphatic glands are much reduced in size.

Colostomy for the Cure of Amœbic Dysentery.—William Norbert Sullivan reports a case which resisted all attempts at treatment. Finally, right inguinal colostomy was performed, the bowel being brought up and attached to the abdominal wall and a few days later incised, while a stream of pyrozone solution was passed through the large intestine, passing out by both outlets, the anus and the artificial anus, thus thoroughly flushing the whole of the large intestine. The patient was kept under this treatment from April to August 30, 1900, when the opening was closed and the bowel dropped back into the abdominal cavity. The pain which had been severe ceased after the first few days. The method possesses two valuable features: (1) It affords rest to an inflamed surface. (2) It permits direct applications of remedial solutions to a portion of the bowel which is practically beyond the reach of injections into the rectum.

Lupus Healed with Roentgen Rays.—William Allen Pusey treated this case. The patient was a woman aged thirty-eight years. The disease had been in progress four years and had extensively infiltrated the chin, neck, and cheeks. The treatment consisted in exposures to *x*-rays after the method of Schiff and Freund, of Vienna. The treatment was continued with necessary intermissions from May 8th to date. Since October 8th there has been no evidence of the disease, and the scars have been wonderfully benefited by the exposures. The results of the treatment are indicated in a photograph presented in this paper.

A Case of Alexia, Mind Blindness, etc., with Autopsy.—Edwin E. Jack describes the case of a man who consulted him for failing vision. Examination revealed a deeper than mere visual trouble. The patient could see letters, numbers, and words, but could not, except to a slight extent, recognize them. Even objects such as matches, keys, photographs, etc., brought no recognition, and other objects which he recognized he could not name. Hearing usually set him on the right track; touch sometimes failed. He could speak fairly well, but would often stop short, the whole mental picture of what he wished to say vanishing. He could write voluntarily a little. Other symptoms developed and the patient died. At the autopsy a glioma and localized softening of the brain were found.

Note on the X-Rays as a Curative Agent in Certain Diseases of the Skin.—Francis H. Williams says that his own experience with the *x*-rays as a curative agent in lupus has demonstrated to him: (1) That excellent results can be obtained by exposing the diseased portion of the skin near a Crookes tube which is giving off *x*-rays, and that the treatment causes no pain, and that it is not necessary to repeat it so frequently as to produce an inflammatory reaction; (2) it is essential that the treatment should be undertaken only by one who has learned how to manage an *x*-ray apparatus and has provided himself with special appliances for carrying out this method.

Philadelphia Medical Journal, December 8, 1900.

Suprarenal Gland in Hay-Fever.—Lewis S. Somers gives his experience in the internal use of this drug; he has carefully observed its effects on twenty-one patients, nineteen males and two females, the youngest being seventeen, and

the oldest fifty-six years. The time during which the patients received the adrenal exclusively varied from one to six weeks, ten being obliged to discontinue the tablets after a week's trial on account of disagreeable symptoms, while seven used them continuously for six weeks and in four they were administered at irregular intervals, but at least one tablet was given daily for two or three weeks. The nasal symptoms, as sneezing, rhinorrhœa, and obstruction to breathing, were but slightly influenced; the sneezing-attacks were apparently more infrequent while the drug was being used, but the attack in itself was as severe as before. The nasal stenosis was somewhat favorably influenced. In about one-half of the cases in which the obstruction was marked there was diminution in size of the engorged turbinals. The pruritus of the chin and buccal membrane was lessened when the tablets were dissolved in the mouth, but when they were swallowed no changes were observed, the same being the case with the eye symptoms, which were not favorably influenced. There was a decidedly unfavorable influence on the asthmatic symptoms. The two methods of administration, as already indicated, are, (1) dissolving a tablet on the tongue and (2) immediately swallowing it. The former method is preferable, as almost no results are observed in the latter. The disagreeable effects noted are: Nausea, a sense of chest constriction, and the development of asthma or the increase of the paroxysm when already existing. The favorable results are slight. Control experiments were made to determine the local effects, showing that the drug was not inert. Its local application is of great value, the writer believing it to be the most satisfactory single remedy that we possess at present.

South African Horse Sickness: its Pathology and Methods of Protective Inoculation.—By A. Edington. This is a disease peculiar to the locality mentioned. The symptoms are thus described: The disease occurs under two forms—the "dikkopziekte" and the "dunpaardeziekte." In the former the head and neck swell up enormously, thus affording trustworthy indications of illness during life. In the latter form, as a rule, no symptoms appear until close to the period of death, when the animal becomes subject to very rapid breathing with heaving at the flanks. At the moment of death, in both forms, it is common to find a huge cloud of white foam ejected from the mouth and nose. This foam is produced from a free exudation of blood plasma into the air-passages. Owing to the fact that the animals suffering from the "dunpaardeziekte" showed no symptoms until toward the end of the period of illness, it had come to be believed that the whole period of the disease was limited to a few hours' duration. The remainder of the article is of interest only to veterinarians.

Fungus Disease of the Ear.—W. K. Hatch and R. Row report a series of cases of fungus of the ear seen in Bombay. They believe that in most cases the condition is a variety of aspergillosis. The symptoms are deafness and pain. The latter is sometimes replaced by a feeling of stuffiness, varying in severity according to the amount of the growth present. In some instances there is a watery discharge. For treatment frequent syringing is advised, with the subsequent use of iodoform and boric acid in equal parts. The article closes with a description of the methods employed in cultivating the fungi on artificial media.

Clinical Lectures on the Causes and Cure of Insomnia.—Sir James Sawyer states that sleep is an appetite; an appetite being, according to Bain, a craving produced by the recurring wants and necessities of our bodily or organic life. The two striking characteristics of sleep are its periodic recurrence and its organic necessity. As to the physiology of sleep, there are two vital changes which take place in this condition: The one is some intrinsic change in those ultimate tissue elements of the brain which are concerned in consciousness; the other is a diminished supply of blood to the brain, especially to the blood-vessels of the cortex. The etiology of insomnia may be considered under two heads, "secondary" and "intrinsic" insomnia. The former may be produced by various evident causes, viz., pain, high fever, frequent coughing, dyspnœa, etc. Sleeplessness of this nature may be controlled by hypnotics or soporifics, or by measures which combat the cause of the insomnia. "Intrinsic" insomnia is said to exist when no objective or obvious physical cause can be discovered. It may be divided into three groups: (1) psychic, (2) toxic, and (3) senile. The subjects of psychic insomnia are generally men, and almost invariably those possessed of the nervous temperament. This state of sleeplessness may follow a severe mental shock, or more commonly it may be subsequent to prolonged mental strain caused by over-study or financial anxiety or arduous literary composition. The cause, whatever it may have been, seems sufficient to rouse a given group of cerebral cells into persistent activity. The arterioles of the brain have no longer that contractility without which sleep is impossible. In these cases probably the initial fault is unnatural excitation of the cerebral cells. In the toxic variety the cause acts primarily upon the blood-vessels of the brain, giving rise to some degree of arterial hyperæmia. The poisons to be considered here are tobacco, alcohol, tea and coffee, and the poisons generated by the gouty diathesis. As to senile insomnia, a person may truthfully be said to be as old as his arteries, not as old as his years. The senile vessels are less elastic and less contractile than normal, and their weakened walls often lead to their permanent dilatation. The smaller cerebral arteries are physically unable to adapt themselves completely to that condition of relative arterial anæmia which is the essence of healthy sleep.

Severe Angina Pectoris Relieved by Oxygen Inhalations.—Charles Steele reports the case of a man aged fifty years, who suffered severely from spasmodic attacks of dyspnœa which were increasing in frequency and severity. Careful dieting relieved his digestive difficulties, and the following was prescribed: sp. eth. sulph. co. ℥xx., tr. digitalis ℥x., bismuthi subnit. gr. x., mucilag. trag. ʒ i., aq. menth. pip. to make one ounce, thrice daily after food; and for the attacks, sp. amm. arom. ʒ i. in an ounce of water, together with inhalations of oxygen. Each attack since this treatment has been cut short at once: the pain, dyspnœa, and horror have been promptly arrested. For six weeks he has had no attack.

The Face and Pupil in Alcoholic Neuritis.—Sir T. Lauder Brunton speaks of the peculiar expression of the face which he has observed in subjects of alcoholic neuritis. The face is mask-like and expressionless, the lips appear to move apart from the cheeks, while the lips themselves seem very mobile. A fixed and unexpressionless band stretches across the nose and cheeks between the eyes and lips, the skin upon the cheeks remaining motionless and unwrinkled, while the lips, eyebrows, and forehead may be moving freely. The condition of the pupil reflex is just the converse of the Argyll-Robertson phenomenon.

The Hydrostatic Test of Stillbirth.—T. Dilworth made a post-mortem examination on an infant that was thought to be born rather precipitately. In examining the lungs they were found collapsed and in a state of "atelectasis." When the hydrostatic test was made, the lungs, entire or when cut into small pieces, sank when immersed. The only explanation seems to be that the infant kept its feeble hold on life by the amount of aeration which the blood received through the trachea and the larger bronchi.

Neurasthenia.—In treating this subject, Lemoine states that there are two clinical forms of this affection—the one, hereditary, is observed in individuals having a nervous or arthritic heredity; the other, acquired or spinal (the hereditary form being rather cerebral). The two fundamental symptoms of neurasthenia are headache and insomnia, both causing much suffering. The headache is rather diffuse than localized. Vertigo is frequent. Speech is rarely affected. Defective memory is quite constantly observed in neurasthenics. Tachycardia is often noticed. The stomach is nearly always dilated. Several theories as to the etiology of this disease have been propounded. Bouchard has concluded that neurasthenia occurs in patients with dilated stomachs. But there are cases with normal digestive functions. Glénard thinks that neurasthenia occurs in patients suffering from ptosis of the various organs. Another theory is that troubles of the genital organs are the causal agent of this malady. The writer believes neurasthenia to be due to a lack in the nervous system of principles which are absolutely necessary to its correct functions. Neurasthenics generally suffer from phosphaturia. The treatment of this malady is very complex. The writer uses the following method: he gives a subcutaneous injection every two days of from 2 to 5 grams of the following solution:

℞	Phosphate of sodium	3 gm.
	Chloride of sodium	2 "
	Boiled water	100 "

This dose of phosphates, although very weak, acts with great rapidity. In Lemoine's experience, patients have, under its influence, come from a state of profound depression into a condition of excitement so marked that he was obliged to diminish or suspend the injections. In addition to this medication, lukewarm douches followed by friction and rest in bed were used. As a tonic, valerianate of quinine may be used. The moral treatment must not be overlooked. Weir-Mitchel's treatment may be tried for serious cases. Electric treatment is also used and is successful with certain cases.—*Le Nord Médical*, November 15, 1900.

Asepsis and the Hands of a Surgeon.—A. Ricard states that gloves in surgery have both their advantages and disadvantages. They should be impermeable. Silk gloves have been unanimously rejected. Rubber gloves may be thin or thick at the convenience of the operator. The former render the sense of touch less obtuse than the latter, but they are more expensive and more easily torn, which is a great inconvenience. Gloves may be easily sterilized. They isolate completely the integument of the surgeon from the field of operation, and from that point of view offer a perfect asepsis. On the other hand, the writer argues that gloves tend to deprive the operator of his delicate touch. He thinks them a source of danger from their liability to become perforated. In conclusion Ricard gives as his own opinion that there are two principal indications for gloves: (1) When a septic case must be operated upon, such as the opening of phlegmons, abscesses, osteomyelitis, purulent peritonitis, etc. (2) When, after contact with septic material, necessity forces the surgeon to undertake at once an aseptic operation.—*Gazette des Hôpitaux*, November 10, 1900.

Hysterical Astasia-Abasia.—Terrien reports a case of this nature which he treated by hypnotic suggestion. Ordinarily these patients are confined to bed, but this patient, a farmer, chose the only method of locomotion which was left to him—transporting himself along by means of his knees, forearms, and hands. The forearms and hands were paralyzed, so he supported himself on his elbows. This paralysis was not attended by disorders of sensation, but was manifestly of an hysterical nature. The patellar reflexes were much exaggerated. This condition had existed for four years. Terrien plunged the patient into a hypnotic sleep and commanded him first to get up, then to walk, then to shake hands, all of which he was able to accomplish. Eight days later he went to work, to the great astonishment of those who had known him.—*Progrès Médical*, November 17, 1900.

Simple Acholuric Icterus.—A. Gilbert and P. Lereboullet conclude that by this term is meant a pathological state characterized by a yellow tint of the skin either more marked at certain points, or generalized, without elimination of biliary pigments in the urine, but with their constant presence in the blood serum. Acholuric icterus is distinguished by its hereditary character and by its relations to the diverse forms of chronic biliary infection (biliary lithiasis, biliary cirrhosis, etc.), which exist either in his ancestors or in the patient himself. But under the term simple acholuric icterus are grouped only the cases in which the acholuric icterus exists by itself without preceding or accompanying the other modifications of chronic biliary infection. The hereditary predisposition appears especially marked in the Israelitish race.—*Gazette Hebdomadaire*, November 11, 1900.

The Therapeutic Use of Salicylate d'Amyle (Ether Amyl-Salicylique or Amylenol).—M. B. Lyonnet states that this new product is obtained by the action of chlorine on a saturated solution of salicylic acid in amylic alcohol. Its formula is $C_6H_4\begin{matrix}OH\\CO_2C_5H_{11}\end{matrix}$. It has hitherto been employed without any inconvenience whether administered externally or internally. Its penetration through the skin is very easily accomplished, as analysis of the urine shows. In different maladies attended by acute or subacute rheumatism it has had excellent results. Its odor is less marked than that of methyl salicylate, and it seems to enjoy an advantage in a good number of cases over this latter drug. It has, besides its antirheumatic properties, the sedative properties of amylic derivatives.—*Lyon Médical*, November 18, 1900.

Münchener medicinische Wochenschrift, Nov. 20, 1900.

The Treatment of Pachydermia Laryngis with Salicylic Acid.—W. Lublinski refers to an article by Fein in a recent number of the same journal in which salicylic acid was highly lauded in the treatment of this somewhat rare disease, and reports the results of his own experience with this drug, which he has used for years. His conclusions, however, based on the observation of twenty-five cases are not quite so gratifying as those of Fein, for while he admits that the salicylic-acid therapy is the only non-surgical treatment likely to be of any use, the good results following its application are never more than temporary. In its etiology and general nature pachydermia laryngis strongly resembles leukoplakia oris, and it is therefore only natural that salicylic acid, which serves so well in the latter affection, should also be of use in the former. The inaccessibility of the parts, however, which makes self-treatment impossible, and the fact that the very essential drying off of the mucous membrane before the application is made, rob the treatment of much of its utility, and relapses are always to be expected. For both diseases a ten-per-cent. solution of the acid in equal parts of alcohol and water, with or without the addition of glycerin, is to be recommended.

The Psychoses of Typhoid.—Deiters says that these may be grouped in three classes: (1) The initial deliria, which are chiefly due to the toxic action of the specific ferment; (2) the psychoses of the febrile period, in which there is also present the damaging effect on the nervous system of high temperatures, and (3) the asthenic forms due to the exhaustion following the course of the disease. Of these it is particularly the first type that is of interest to the general practitioner, and he describes two cases affecting the children of neurotic parents in which various irrational manifestations (restlessness, hebetude, uncleanliness, violence, inability to answer questions rationally, etc.) were observed a week or ten days before the onset of specific symptoms. The conclusions are that when a rise of temperature is accompanied by acute psychical derangement typhoid should be thought of, and that the initial delirium of the disease may persist for some time without any temperature elevation or the appearance of the usual symptoms.

A Case of Foreign Body in the Nose.—Breitung reports a case in which the foreign body, a button, was removed from the nasal cavity of a three-year-old child by inflation through the opposite nostril, the mouth being closed, followed by extraction with aural forceps when it had been brought within reach. The difficulties in this instance had been much increased by a previous unsuccessful attempt

at removal by the family physician, and the author makes a plea for the early calling in of the specialist in such cases.

Connective-Tissue Induration of the Heart Muscle (Myofibrosis Cordis).—K. Dehio reiterates his statements concerning the heart lesion to which he has given this name, and which have lately been called in question by other writers. The essential point of difference between this and other forms of degeneration described appears to be the fact that it is universally diffused throughout the entire substance of the muscle instead of being limited only to small areas. The process is an exaggeration of the increase in the connective-tissue groundwork of the muscular structure of the organ, which is a normal senile change, but which may be found as a pathological manifestation at any age. In well-marked cases the lesion is unmistakable: the usually angular, polygonal cross sections of the muscle bundles have become circular, and are widely separated by the new-formed tissue. In advanced stages the fascicles themselves are invaded and each individual fibre lies embedded in connective tissue. Changes take place in the fibres also, which may be hypertrophied in some regions, while in others, owing to the pressure, they become atrophied and seem to be in process of replacement by the new growth. The lesion appears to be a direct consequence of hypertrophy and dilatation, which view is borne out by the fact that it is never found except where such changes have taken place, and also because it is always most marked in the auricles, which are the first portion of the heart to feel the effect of overstrain.

Traumatic Diabetic Coma.—W. Spitzer contributes the history of a case in which a fatal attack of diabetic coma was apparently induced by a combination of trauma and psychical shock. The patient, a man aged forty-six years, had been suffering for six years from a diabetes of moderate severity with a daily excretion of from gr. lxxv. to cl. of sugar without any subjective symptoms or disturbance of nutrition. Under these conditions a fall resulted in fracture of the right clavicle, while in addition to the actual injury the very emotional patient sustained a profound emotional shock. In spite of energetic stimulation and the administration of large amounts of alkalies the symptoms of developing coma appeared, which finally became complete and ended fatally six days later. Severe psychical disturbance in predisposed individuals seems greatly to increase an existing glycosuria, while there is no immediate provision for preventing the formation of abnormal organic acids. In addition, owing to the sudden onset of this condition of acidosis, the organism is unable to cope with it by the usual processes of oxidation, which suffice in cases of long standing, the organism being, as it were, "startled" out of its normal means of self-defence.

The Pathogenesis and Therapy of Asthma.—Cohen-Kysper considers the usually accepted theory that this disease is in most cases a reflex neurosis depending on stimuli affecting the respiratory mucous membrane in some portion of its extent as erroneous, and would substitute the view that it is the consequence of some nasal conditions, most often a stenosis. This, even though the patient may be quite unconscious of its presence, in the course of time in predisposed individuals produces a state of respiratory hyperæsthesia, or increased consciousness of the normal respiratory sense, which eventually leads to the various forms of the malady known as pseudo-asthma. In every case of true asthma in which there are distinct pulmonary changes present, this factor, a psychical reflex as it were, also plays a large part, especially in those attacks coming on in close rooms, in a heated atmosphere, at night, etc. The treatment is obvious from this view of the etiology and consists in a thorough search for and removal of any existing nasal abnormality.

The Use of Hydrogen Peroxide in Wound Treatment.—Oskar Müller warmly recommends the routine employment of this agent, which apparently has not yet reached the same popularity abroad that it enjoys with us. Its advantages are its very powerful bactericidal action; its property of undergoing catalysis and splitting up into water and free oxygen when in contact with bacteria, pus, etc., whereby the remotest recesses of a suppurating cavity are reached and a mechanical cleansing is effected by means of the active gas liberation; its great value as a deodorizing agent; its absolute harmlessness to skin or mucous membranes; the absence of toxic symptoms after absorption, and finally its cheapness.

Sympathetic Ear Disease.—Rhese describes three cases in which after excision of the malleus of one ear for chronic middle-ear disease a very notable and permanent improvement followed in the hearing of the other ear, which had been subjected to no therapeutic measures. In explanation the author offers the hypothesis of an anastomosis between the two auditory nerves through which possibly inhibitory stimuli may pass from the diseased to the well organ, which impulses cease as soon as their causes (the cicatricial contraction, circulatory changes, etc.) are removed.

A Case of Malarial Cystitis.—William F. Benart reports the case of a man who suffered at about noon every day from pain, uneasiness, vesical tenesmus, and painful urination, the attack reaching its maximum between 3 and 6 P.M., lasting from one to three hours, and gradually ceasing. The urine was laden with pus. There were no symptoms pointing to malaria excepting the periodicity of the attacks—no chills, no rise of temperature exceeding four-fifths of a degree; but the patient was troubled with sleeplessness, poor appetite, a worn-out feeling, and a gradual loss of weight. When it was noted that every other day the symptoms were more severe, malaria was suspected, and quinine sulphate given as follows: 7 A.M., gr. ix.; 12 M., gr. ix.; 3 P.M., gr. iii. The second day the symptoms began to subside, and by the fifth day had nearly disappeared. A specimen of the blood showed the presence of the malarial parasite.

A Case of Cirrhosis of the Liver and of the Pancreas, with Diabetes and Hæmachromatosis.—A. P. Condon describes a case, and says that regarding the etiology of bronze diabetes three theories may be mentioned: (1) That it is a distinct pathological entity—advanced by Marie and supported by Hanot and other French writers; (2) that it is a diabetes mellitus, the diabetic poisons producing the hæmachromatosis, cirrhosis of the liver, pancreas, etc.—advanced by Letulle; (3) that hæmachromatosis is the primary affection, and the deposition of pigment causes the hypertrophic cirrhosis of the liver and pancreas, diabetes resulting when the pancreatitis reaches a certain stage—advanced by Opie.

University Medical Magazine, November, 1900.

Nature and Distribution of the New Tissue in Cirrhosis of the Liver.—The following conclusions are reached by Simon Flexner: 1. In all forms of cirrhosis the white fibrous tissue is increased. 2. Along with the increase of white fibrous tissue there is a new formation of elastic tissue. This new elastic tissue is derived from pre-existing tissue in the adventitia of blood-vessels and the hepatic capsules. 3. Both white fibrous tissue and elastic tissue, in all forms of cirrhosis, may penetrate into the lobules. This penetration takes place along the line of capillary walls or follows the architecture of the reticulum. The chief distinctions between the histology of atrophic and hypertrophic cirrhosis depend upon the degree of extralobular growth and the freedom with which the lobules are invaded. In hypertrophic cirrhosis there would appear to be less interlobular growth and an earlier and finer intralobular growth. 4. The alterations in the reticulum, *per se*, consist, as far as can be made out at present, of hypertrophy rather than hyperplasia of the fibres. It is still uncertain whether any of the differential methods now in use suffice to distinguish between the reticulum and certain fibres derived from the white fibrous tissue of the periphery of the lobules.

The Dissemination of Tubercle Bacilli by Cows in Coughing a Possible Source of Contagion.—Mazijck P. Ravenel

gives the results of numerous experiments on this subject. In order to collect the sputum from tuberculous cows he made use of an ordinary nose-bag, near the bottom of which is placed a shelf of soft pine wood, sterilized by steam heat each time before using. The wood catches the smallest particles ejected by the cow during the act of coughing. The more solid particles may be removed by a platinum needle for experiment. Tubercle bacilli have been detected in the bronchial secretions of every tuberculous cow on which the experiment has been tried. Of forty-five guinea-pigs inoculated in the peritoneal cavity with the tuberculous mucus, twenty-three died within a few days, most of them from peritonitis, too early for the development of tuberculous lesions. Of the remaining twenty-two, eleven, or fifty per cent., became markedly tuberculous. Fourteen guinea-pigs were exposed by means of a special nose-bag directly to the breath of the tuberculous cows, and after several weeks were killed. No evidence of tuberculosis could be detected in any of them.

The Justus Test in Syphilis: its Application in Twenty-nine Cases.—H. M. Christian and Otto H. Foerster from their investigations draw the following conclusions: 1. That in the diagnosis of doubtful ulcers it is of no value. 2. That it seems to occur in a certain proportion of cases of acute secondary syphilis, where it appears to be a symptom of the disease and can in no sense be considered a true test, as the diagnosis in such cases is already complete. 3. That as a test it is unreliable, occurring as it does in conditions other than syphilis.

Aneurism of the Aorta Treated by the Insertion of a Permanent Wire and Galvanism (Moore-Corradi Method).—Guy L. Hunner feels convinced from study of the literature that this malady is usually a surgical disease. The wire which the writer believes quite ideal for this operation is a silver alloy, highly drawn; seventy-five parts of copper to the thousand makes a wire which when drawn from No. 8 to No. 27 (standard gauge) takes a closer coil than steel; it is also more pliant than steel, thus minimizing the danger of puncture should the end come in contact with the thin aneurismal wall. It can more easily be passed into the needle without kinking than the pure silver wire, for it has more body. It erodes more than steel, thus having a rougher surface for whipping out fibrin. The writer believes, however, that the formation of fibrin is far more a chemical than a mechanical process; and silver, being one of the metals least resistant to the electric current, transmits more of a given current for action on the blood. The positive pole of the galvanic battery is connected by means of its insulated conducting cord with a long end of the wire from the aneurismal sac; the negative pole is connected with a metal plate at the back. The sac should never receive both poles, and the current should not be so passed that the negative electrode is in the sac. In thoracic aneurism, operated on by the method described by the writer, the patient does not require an anæsthetic. Locally, cocaine or ethyl chloride may be used. In abdominal cases the usual preparations for cœliotomy are made. Abstracts of the cases treated by the wire method, and of those treated by passing electricity through a permanent wire are then given. The writer adds a report of the five cases which have been operated on at the Johns Hopkins Hospital. A review of the cases treated by the two methods mentioned above, with their results, certainly argues for the efficacy of the Moore-Corradi method. Clinical and post-mortem evidence is also in its favor. Its great drawback is the difficulty of accurate diagnosis. The cases under consideration were not picked cases, but were generally considered hopeless. When, too, it is considered that the method is still in its infancy, it seems still further to merit great consideration.

Oxygen and Steam with the Vapors of a Special Mixture in Pulmonary Diseases.—By Clement A. Penrose.

Obstetrical Paralysis, Infantile and Maternal.—By H. M. Thomas.

Archives Générales de Médecine, October, 1900.

Endocranial Complications of Sphenoidal Sinusitis.—M. Joubert calls attention to the fact that (1) the sphenoidal sinuses may become inflamed in nasopharyngeal infections, especially during the course of certain general affections, such as grippe, pneumonia, erysipelas, typhoid fever, etc., and this much oftener than is generally supposed. (2) The sphenoidal sinuses may become complicated by fatal meningitis or phlebitis, the infection being carried by an osseous or venous passage or by means of the lymphatics. Many cases of so-called spontaneous meningitis may be due to an unrecognized sinusitis. (3) The diagnosis of sphenoiditis is extremely difficult, the symptoms being variable and not very definite. Catheterism or puncture of the sinuses is the best method of diagnosis. (4) Treatment of complicated sphenoiditis is merely prophylactic, and consists in prevention of infection of the sphenoidal sinus; or in the treatment of the inflammation if it be already present.

Two Cases of Uræmic Hemiplegia with Autopsy.—L. Brodier, from a study of these and other cases, concludes that uræmic hemiplegia may in exceptional cases persist for several years. It is then accompanied by no trophic or vasomotor disturbances of the paralyzed parts, but death occurs in the midst of other symptoms of uræmia of the nervous system, such as Jackson's epilepsy, delirium, or coma. In all cases of hemiplegia accompanied by albuminuria the physician should remember the possibility of a renal origin of the functional disorder, and search for evidences of chronic nephritis, or for other symptoms of chronic uræmia. The mere coexistence of renal insufficiency and hemiplegia do not suffice for the assertion that the motor trouble is due to uræmia. When hemiplegia of some duration is found in a patient suffering from chronic nephritis, the absence of exaggerated reflexes, of Babinski's symptom, and of trophic or vasomotor phenomena should cause a suspicion of the uræmic nature of the paralysis.

Clinical Forms of Paralysis of the Brachial Plexus.—Henri Grenet says that there are as many forms of paralysis as there are segments of the plexus, but the only two real clinical types are paralyses of radicular type and those of a terminal type. The former are characterized by the localization of the trouble in a special group of muscles and by the zone-like arrangement of the anæsthesia. Paralyses of a terminal type are recognized by the localization of the trouble to the area of one or more peripheral nerves. Hysteria may be recognized by the mode of distribution of the sensory troubles (also by other evidences of neurosis). Paralyses of the peripheral nerves may simulate those of a radicular type when several nerves are attacked simultaneously, or when the affection extends into the territory of neighboring nerves.

OUR LONDON LETTER.

(From our Special Correspondent.)

WAR HOSPITALS COMMISSION: THE COMING REPORT—MEETING OF ROYAL COLLEGE OF SURGEONS—VAGINAL HYSTERECTOMY FOR CARCINOMA UTERI—OSSEOUS DISEASE—LATE OR CONTINUED RICKETS—PULSATING SWELLING OF THYROID—PRINCE OF WALES' HOSPITAL FUND—THE LATE DR. COCKLE.

LONDON, November 23, 1900.

It is said that the report of the commission on the war hospitals will be ready for presentation when Parliament meets. Accordingly attempts to forecast the tenor of the report are being made. That regrettable incidents happened will scarcely be overlooked, but it will probably be made clear that these were unavoidable under the system which exists and under the stress of active war. Will reorganization of the medical service be recommended? That is the question which most interests outsiders. It is almost certain that changes will be recommended with the intention of rendering the service more attractive, and that the actual grievances which remain unredressed will be distinctly condemned. I claim no telepathic communication for my anticipation: the grievances are so obvious to all who look into the matter. The commissioners are independent and will not be afraid to tell the government that the army surgeons must be treated better as to pay, allowances, and study furlough. The report will endorse the claims of the doctors and justify them before the public. Perhaps the government with this support and with no longer the opposition of Lord Wolseley and his gang will decide to do justice to the service.

A good deal of nonsense has been written about orderlies by editors and correspondents who seem unable to distinguish a trained male nurse from an untrained helper. Of course a war-hospital orderly is a soldier, but his training as a nurse is very complete and careful. A certain num-

ber of women will not see this because they are so set upon pushing women into every possible office. In deference perhaps to this outcry a number of additional female nurses were engaged during the war, but the experiment was not successful enough to encourage the authorities to continue it, and a number of the women who had been temporarily employed, on applying for permanent engagements have been told that there are no vacancies and that none is likely to occur.

The hospital orderly may no doubt be improved; so may the female nurse, if her hysterical patronesses will suffer such an assertion. The orderly's education may be somewhat improved, but his hospital training is quite as good as that of the females in civil hospitals, and, as I said, he must be a soldier too. Novices, even civilian consulting surgeons, are not necessarily the best judges of the requirements of an active campaign; nor are war correspondents, with all their critical powers. A good illustration of this was Mr. Julian Ralph, a brilliant correspondent, but by no means infallible. Any medical man who reads some of his letters in which medical matters are mentioned will see how incompetent he is to discuss them.

The meeting of fellows and members of the College of Surgeons was duly held on the 15th, when the council was once more urged to agree to some degree of representation of members. A resolution was in fact passed *nem. con.* asking the council "not to carry into the new century the unfortunate controversy which has existed so many years with disastrous results."

Another resolution requested the council "to take any steps in its power toward obtaining a parliamentary inquiry into the working of the medical acts, with a view to their amendment." This was allowed to stand on the minutes, but the president, Sir W. MacCormac, in his address mentioned that the council considered it somewhat out of order, as the matter concerned the General Medical Council rather than the college. Mr. George Brown, who brought forward the motion, is a member of that general council, but thought it no use to look in that direction. He also said men who held a double qualification ought to be allowed to use the prefix "Dr." This remark elicited from the president the statement that application was made by the college in 1888 for this privilege but was refused.

A claim was put forward for the members to have the annual report posted to them as it is to fellows. The only objection is the wasteful expense of posting a document nobody wants. Any one can have a copy on asking for one by a post card; but it was said only six members had asked for one during the year.

There was a further resolution on the question of combining with the Society of Apothecaries and on the recognition of science courses in ordinary schools. The latter subject is still under consideration and the former is perhaps not opportune while the newly organized university is getting into working order. But both these questions I have dealt with in former letters.

The closing meeting of the century will probably be as fruitless as its predecessors, and reformers must look to the future and show more earnestness and determination.

Dr. A. H. N. Lewers read a paper at the Medico-Chirurgical Society on the 13th on the "After Results of Vaginal Hysterectomy Performed for Cancer of the Uterus." He gave some account of forty cases, in twelve of which there had been no recurrence. Omitting one case in which little more than a year had passed since the operation, in eleven cases (27.5 per cent.) the patients remained well from two to seven years after the operation. Dr. Lewers attributed this large percentage to careful selection. He examines under anæsthesia and operates only if the disease seems to be limited to the uterus itself. He performs supravaginal amputation of the cervix only for very early cases, and for cancer of the vaginal portion in which the growth is limited and superficial.

In each of the twelve non-recurrent cases the specimen had been reported on by Mr. Targett, and Dr. Lewers gave very full details of the evidence of non-recurrence. He concludes that in a certain proportion of cases the relief by operation may continue so long (seven years or more) that it may probably be permanent, though this proportion must be small so long as patients seek relief only at a late stage. The great desideratum is early diagnosis. As to this it is most important to recognize the grave significance of bleeding after the menopause, or at an earlier age between the menstrual periods. Another point, almost as important, is that patients may look quite well and fat for a long while after cancer of the uterus has set in. Dr. Lewers exhibited specimens and illustrations of his cases and an interesting discussion followed.

Dr. Briggs, of Liverpool, said he had operated on eighty-three cases of malignant disease. Up to April, 1899, he had fifty-seven cases with three deaths. Of these, one was sarcoma of the cervix without recurrence; fifty-six were cancer—ten of the body, forty-six of the cervix. Of these patients ten are living now, but in five of them recurrence has appeared. In malignant adenoma the results are better than in cancer. He thought Dr. Lewers' paper encouraging.

Dr. Amand Routh had operated on forty cases—fourteen of the body, twenty-six of the cervix. Of the fourteen, recurrence took place in three within twelve months, and in one in seventeen months; one patient was well after two and one-quarter years, one after three and one-half years, and one after four years. Of the twenty-six cases of cervical cancer, the disease recurred in several within a year; one very disappointing case recurred after seven years. One patient operated on in 1892 and another in 1895 are now alive.

Mr. Bowerman Jessett, who has performed the operation one hundred and fifty times (one hundred and seven cases having been published last year), said his results quite justified Dr. Lewers' conclusions, and he added that cases of fibroid which became malignant were favorable. To this remark objection was taken by subsequent speakers: Dr. Champneys said he had seen only one case in which such a change seemed in any degree probable, and Dr. Lewers could not admit that fibroids might become malignant.

Mr. Charles Ryall, commenting on the comparative frequency of recurrence in cancer of the cervix, attributed it to reinfection of the wound during operation, and related a case illustrating this explanation. On this Dr. Herbert Spencer expressed extreme interest, as he was certain there was great risk of implanting the growth upon the vagina, vulva, or other parts wherever there might be a scratch or abrasion. This risk had often induced him to do a high amputation and to use the cautery. The entire operation could be done by cautery, as shown by Dr. Byrne, an American surgeon who has done some four hundred operations by it with only one death.

Mr. Walter Tate regretted that Dr. Lewers had not separated his cases of cancer of the body and cervix, and he thought, too, the operation was justifiable even when it did not give permanent relief.

At a "clinical evening" of the Medical Society on Monday last, several interesting cases were shown. Mr. Kellock showed a female child, aged seven years, suffering from what he diagnosed as mollities ossium, although he said that it might better be described as fragilitas and mollities, as was a case of Mr. Dents, recorded in the transactions. Multiple fractures occurred, and tenderness and pain at the site of fracture preceded the occurrence. The first fracture occurred when the child was five months old.

Mr. Muirhead Little showed the radius and femur from a case of late or continued rickets. The patient, a girl aged seventeen years, was exhibited to the society last April, and although on that occasion one speaker had insisted that it was not a case of rickets, but of mollities or some such condition, these specimens showed the characteristic changes of rickets in and about the epiphyseal lines, thus proving the correctness of the diagnosis. This patient died after two days' illness with symptoms of acute cerebral disturbance. He had now under his care a lad aged seventeen years, with marked enlargement of the epiphyses and severe knock-knee, whose bones were quite soft, containing little lime salts, as shown by the *x*-ray and by the trifling resistance offered to the osteotome in Macewen's osteotomy. He hoped to exhibit the case later on.

Dr. Caley showed a pulsatile swelling of the thyroid (aneurism, sarcoma, or cyst?). Mr. Weeks showed a rare case of locomotor ataxia in a boy aged eight and one-half years. He had nearly all the symptoms of the disease, which was said to be congenital. The father had locomotor ataxy, but no other member of the family as far as known. Various cases of skin disease were shown, and one of Baker's cyst of the leg.

The great demands on the public for the war and famine funds have had an adverse influence on the finances of our hospitals, some of which are suffering severely from diminished subscriptions. Even the Prince of Wales' hospital fund has been affected, and an appeal on its behalf is now being circulated. It is hoped that £25,000 may be given before the 15th prox. It is unfortunate that this fund to some extent duplicates the Sunday fund. If the Prince had kept the committee clear of the persons whose administration of the Sunday fund has given offence it would have greatly helped this appeal.

John Cockle, M.D., M.A., for many years physician to the Royal Free Hospital, died on the 14th inst., aged eighty-seven. He was also at one time a teacher in the now extinct Grosvenor School. He retired from practice some years ago. Prior to that I used frequently to meet him. He was a very courteous and genial man, with abundant information. He was scholarly, too, a fact recognized by his university, which confirmed on him its honorary degree in arts. He was a fellow of both the royal colleges. There is in the Hunterian Museum a specimen from a case of aneurism of the arch of the aorta on which at his request Mr. Heath operated by tying the left carotid. The patient lived four years. Dr. Cockle had for a long time given attention to thoracic aneurisms, and had found records of what appeared to be cures from obliteration of the carotid.

Society Reports.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, November 19, 1900.

PARKER SYMS, M.D., PRESIDENT.

Myoma Uteri.—DR. GEORGE TUCKER HARRISON presented a large myoma which he used as a text for some remarks on the method of removal. He said that every myoma at first was interstitial, and he was of the opinion that by proper treatment such a tumor might be made submucous and removed after the manner employed in obtaining this specimen. The patient, an elderly single lady, had been treated by him at first by the administration of thyroid extract, as she had refused radical operation. Subsequently she had consulted him because of irritation of the bladder, and examination had shown this to be caused by an effort of nature to rid the uterus of the tumor which had been converted into a submucous myoma, largely, he believed, as a result of the treatment employed. The tumor was so large that it had been necessary to make two deep lateral incisions into the narrow vagina in order to get sufficient room to deliver the tumor. After this had been done he had sutured these incisions. He would not at the present time make use of the thyroid extract, because it produced great emaciation, and its use was attended by certain dangers. He preferred now to employ the suprarenal extract, which had served him well in controlling the hemorrhage. The method employed in this case was, of course, not applicable to cases in which the tumor was so large that it could not descend low into the pelvis, or in which the uterus had not already made efforts to expel the growth. A necessary preliminary to the operation was dilatation of the cervix by instruments or by the insertion of laminaria tents. During the removal of the tumor there was always danger of entering the peritoneal cavity. The great advantage of the method was its freedom from shock.

General Septic Peritonitis.—DR. IRVING S. HAYNES read a paper on this subject. He defined the term "general septic peritonitis" as an inflammation of the peritoneum, septic in origin, and unlimited in extent by adhesions." It might originate from many sources of infection. Thus in the fifteen cases forming the basis of the paper eight had been caused by rupture of the appendix, while others had originated from rupture of cancer of the bowel, rupture of pus tubes, extension of sepsis from the uterus after an abortion, traumatism of the abdomen, etc. The affection was conveniently divided into three stages: (1) the stage of shock; (2) the stage of reaction, and (3) the stage of recovery, or of collapse and death. The vomiting at the beginning was due to shock, and was not significant unless it persisted after a washing-out of the stomach and bowel, and the vomited matter consisted of the contents of the bowel. In the adult cases seen early, the pulse had varied from 90 to 120 and the temperature from 101.6° to 102° F., and the respirations had been rapid and shallow. The pulse was thin, thready, and weak—the pulse of shock. In the cases that had ended in recovery the pulse had at first been 100, and in the cases that had terminated fatally had been about 130, thus pointing to the early infection of the system in the grave cases. A short time before death the temperature began to rise, but rarely went above 104° F. One of the earliest signs of recovery was a more restful facial aspect. These patients died unless operated upon, and the only hope lay in removing the infectious material by an early abdominal section. His operative cases had been operated upon on an average within four hours after the infection. While one might be sure that death would occur without operative intervention, it was not so certain that operative intervention would be followed by a fatal issue. Every now and then, even an apparently hopeless case would end in recovery; hence it should not be assumed that death was inevitable, and that, therefore, nothing should be done. In all doubtful cases the incision should be made through the linea alba. The character of the fluid which gushed out would give a clew to the locality of the trouble. The abdominal cavity should be at once thoroughly irrigated, by means of a large glass tube perforated laterally, with a very large quantity of decinormal salt solution. This irrigation should be kept up until the fluid returned clear, and should be done without sponging before a search was made for the lesion. The handling and chilling of the intestine should be most carefully avoided. When there was great distention of the bowel, interfering with the necessary manipulations, the gas should be allowed to escape through a small linear incision, which should afterward be closed by suture. Full strength peroxide-of-hydrogen solution could be used locally, if followed by a washing with salt solution, but he would not advise its use throughout the peritoneal cavity as it certainly possessed the power of injuring the epithelium. Probably the best form of drain was the "wick drain," made by wrapping strips of gauze in gutta-percha tissue. The dressings should be frequently renewed to favor capillary drainage. The speaker cautioned against overstimulation of the heart by hypodermic injections of caffeine, strychnine, sparteine, and similar drugs, but did not think there was much likelihood of overstimulation from all the whiskey that would be given with a hypodermic syringe.

DR. CHARLES N. DOWD said that not long ago a case of general septic peritonitis was considered necessarily doomed, yet quite recently cases had been reported from almost every hospital in this city with an encouraging percentage of recoveries. A large number of surgeons were in the habit of flushing out the peritoneal cavity with warm saline solution; others depended upon their ability to wipe clean the surfaces of the intestine, and did not wash out the peritoneal cavity; others depended largely upon incisions made into the intestine with the object of liberating the intestinal contents and diminishing the distention, and in this way restoring the function of the peritoneum. All of these methods had, in certain instances, given good results. It was noticeable that the successes and failures in this class of cases from different hospitals occurred in groups. The inference from all the foregoing considerations was that the good results were not dependent upon the particular methods employed. In studying the course of peritonitis it would be noticed that at the beginning there would be a small spot of inflammation and the effusion of a considerable quantity of serum. Most surgeons paid no special attention to this effusion. Later on, however, it would be found that this serum became cloudy, indicating that the infection had gone somewhat farther. Still later, one would find an effusion of seropus. The successful cases had been, generally speaking, those in which the general peritonitis had been mild, the serum being but slightly cloudy—in other words, they were border-line cases. It was true there might be thick pus at the site of the infection. When flakes of fibrin were scattered all through the intestinal coils, and thick pus was matted over the bowel, or localized abscesses had formed, recovery seldom, if ever, occurred. Many patients would recover simply by drainage of the infecting abscess. There could be no doubt that at the present day the majority of sur-

geons favored the free use of hot saline solution. The power of the peritoneum to deal with sepsis was certainly great; hence the confidence placed by experienced surgeons in mere irrigation and drainage. However, ten years ago drainage had been used far more frequently than at the present time. The surgeons of to-day preferred to use moderate drainage and supplement this with means for increasing peristalsis. The tapping of the intestine at one or more places was looked upon as an additional means of increasing peristalsis.

Dr. Benjamin T. Tilton thought general septic peritonitis offered a peculiarly favorable field in hospital practice for improving the mortality statistics. Modern methods had already greatly improved the statistics. The older methods of treatment by opium and rest of the affected parts had yielded a mortality of ninety-five per cent. or more, whereas the more recent methods had reduced it to eighty per cent., and in some instances as low as sixty per cent. There must necessarily be a large number of fatal cases, as for instance from sudden invasion of the peritoneal cavity and a general poisoning before operation could be undertaken, or cases which might have been favorable had they been brought to the surgeon sooner. Cases in which there were numerous pus foci walled in by adhesions did not come under the class considered in this discussion. When nature had made any attempt to limit the exudation of pus by adhesions, one had reason to hope for recovery. He did not look for any great improvement in the present surgical technique; progress in this department of surgery must rest chiefly upon the co-operation of the medical profession in bringing these desperate cases earlier to the attention of the surgeon. He was opposed to the method of wiping off the intestine, because it was inadequate for the removal of the pus and bacteria, and inflicted a certain amount of trauma.

Dr. A. Brothers said that Dr. George R. Fowler, of Brooklyn, had suggested that in cases in which the peritoneal cavity was full of pus, the elevation of the foot of the bed was contraindicated; instead of this the head of the bed should be raised in order to favor the escape of pus. The speaker said that he had tried this method, and had been convinced that the sepsis had been diminished by the adoption of this practical suggestion. As his experience in abdominal surgery had increased, his confidence in the power of the peritoneal cavity to take care of a limited amount of infection had increased. Formerly he had been in the habit of flushing the peritoneal cavity frequently; now he did it only in cases in which a very large quantity of pus was already distributed throughout the peritoneal cavity, for in ordinary cases of general septic peritonitis such flushing seemed to him to do more harm than good by disseminating the septic matter into the remotest parts of the peritoneal cavity.

Dr. John F. Erdmann said that he was disposed to agree with the last speaker rather than with the others as to the technique. In many cases showing pus foci he simply cleansed the cavity with a sponge moistened with peroxide of hydrogen, following this with the application of a sponge moistened with decinormal salt solution. After twenty-four or forty-eight hours he endeavored to discard all drainage. He certainly agreed with the preceding speaker that the flushing with salt solution served to disseminate the septic matter rather than to cleanse the peritoneal cavity.

Dr. Haynes, in closing, said that he believed the most virulent cases were those in which the infection was due to the bacillus coli communis. His experience led him to think that most patients operated upon within six or eight hours after infection would recover, while those operated upon after that time would usually die. He could not agree with those who had spoken against flushing with salt solution, and did not believe that this irrigation would tap the lesser cavity of the peritoneum. When it was suspected that the infection was present there, this cavity should be opened and cleansed.

The Use of Hot-Water Vaginal Injections.—Dr. James Hawley Burtenshaw read this paper. He said that old as this therapeutic measure was he believed it was more commonly misunderstood and more generally abused than almost any other popular mode of treatment. The distinction should be sharply drawn between the cleansing and the therapeutic vaginal douche. The application of the douche for four or five minutes served only to increase the pelvic congestion. At least three gallons of water at a temperature of 107° to 120° F. should be used for each douche, and the douche should be taken twice daily, the patient having been instructed to remain in the recumbent position for at least half an hour afterward. On account of the large quantity of water employed, it would be found most convenient for the patient to take such a douche while lying in a bath-tub, provided the latter was of sufficient size. The hips should be raised while the douche was taken. It was not generally advisable to add antiseptics or other medicaments to these douches.

Dr. George Tucker Harrison said that he heartily agreed with all that had been said in the paper about the method of giving vaginal douches. In this connection he wished to give full credit for this most important therapeutic measure to its originator, Dr. Thomas A. Emmet, who had first brought it to the notice of the profession in 1862. In cases of parametritis following childbirth he had seen most wonderful results from a proper use of the hot vaginal douche.

Harmful after Certain Operations.—Dr. J. Riddle Goffe said that he was in accord with the general views expressed in the paper, yet he had not made use of such large quantities of hot water. He had often advised the use of a hinged board fitting over the bath tub. When this could not be conveniently arranged, the woman should be directed to lie down on the bottom of the tub and take the hot water from a combination faucet. It was the custom in the Woman's Hospital to use hot douches after curettage and perineal operations, yet he felt sure that this practice was harmful in that it caused anæmia of the parts, and interfered with the healing-process. He much preferred in such cases to make use of a light vaginal tampon. The use of hot douches after vaginal hysterectomy was often responsible for a sluggish granulating process because of the maceration of the tissues by the retained douche water. It had been suggested that hot vaginal douches of short duration might be useful when it was desired to aid the development of imperfectly formed pelvic organs, but to this he could not subscribe, for congestion of the venous circulation did not seem to him a rational method of trying to accomplish this.

Contraindications.—Dr. F. P. Hammond expressed the opinion that the quantity of water used in the douche was of little consequence. The important point to consider was the duration of the douche, and as good results could be secured from the use of one gallon of fluid as from three gallons, provided the aperture of the nozzle was sufficiently small. The douche was entirely contraindicated in pronounced anæmia, especially when there was marked headache, because with an effective vaginal douche from one-third to one-half of the blood in the body was forced into the pelvis. It was a safe rule to interdict the use of the hot vaginal douche until the anæmia had been at least partially controlled. The douche was also contraindicated in acute perimetritis or salpingitis, be-

cause it was not always easy to say whether or not pus was already present, and the hot douche would certainly favor suppuration. In cases of uterine dysmenorrhœa without marked involvement of the ovaries, a prolonged hot vaginal douche would often give complete relief. It did this by softening the cervical mucosa and relieving the tension.

Dr. W. Evelyn Porter said that it had been his practice for several years to have his patients make use of a vulvar pad with an outlet tube of smaller size. The nozzle was held in place by a T-bandage, and the outflow was regulated by pinching the tubing more or less. This gave a prolonged douche with a moderate quantity of water, and at the same time distended the vagina. The vulvar pad and the Kemp's tube would accomplish this nicely, and would require the use of only from four to six quarts of water.

Dr. A. B. Tucker said that he had found that by the use of large hot vaginal douches it was possible to do so much good in cases of retrodisplacements that pessaries would be rarely required.

Dr. F. H. Wiggin said he firmly believed that this method was far more useful in 1862 than at the present time when there were other and better methods of treating acute inflammatory diseases of the female pelvic organs.

Dr. A. Palmer Dudley said that hot vaginal douches were not used much at the present time by the younger practitioners because it was known that their action did not reach beyond the cellular tissue. The treatment had been introduced by Dr. Emmet at a time when the theory of cellulitis had dominated gynæcology. He thought Dr. Emmet had lived long enough to see many of the younger men go out of the Woman's Hospital with different notions as to the value of these douches. His own point of view being surgical he could see but little need at the present day for such treatment.

NEW YORK ACADEMY OF MEDICINE.

Anniversary Meeting, December 6, 1900.

William H. Thomson, M.D., President.

Appendicitis from the Medical and Surgical Points of View.—This was the topic of the anniversary discourse, which was delivered by Dr. Robert Abbe. He called attention to the fact that appendicitis had held its own in the surgical field in spite of prejudice and of the new and interesting problems constantly arising. The experienced surgeon often treated at the present time as many as one hundred cases a year. The question was often asked, Why was so much heard of appendicitis at the present day when it was an almost unknown affection a few years ago? The answer was to be found in the different nomenclature formerly employed. Most of the cases now designated as appendicitis were formerly spoken of as attacks of inflammation of the bowels. The first attack of appendicitis recognized by the patient was probably the terminal stage of the disease, because examination of the appendix showed stricture, and it was well known that strictures usually required a long time for their formation. It was true that strictures might sometimes form rapidly, but even in these cases one would usually find behind them concretions, and certainly these masses had required a long time to grow. With some recent writers the erroneous idea still prevailed that these concretions formed in the colon and dropped into the appendix, but the fact that the concretion was always on the distal side of the stricture negatived this view. In no case had he not found concretions detained there by strictures, and the concretions would always be found packed in close to the stricture. These concretions acted as a ball-valve. It had been seriously suggested that gout might be a cause of appendicitis, but it should be remembered that appendicitis occurred largely in childhood, that it was a bacterial infection, and that the type of joint disturbance was a low grade of pyæmic infection. The speaker objected to the term "chronic" appendicitis, preferring to speak of the condition as latent appendicitis, because the latter term indicated that in the interval the presence of appendicitis might not be capable of detection. In considering the statistics of medical and surgical treatment of appendicitis one should bear in mind that every case coming to the surgeon represented on an average from five to twenty medical cures. It could not be denied that in a very limited number of cases nature was competent to deal with the gravest conditions, but the statistics of such cases showed a far higher mortality than the cases that had been promptly treated by operation. One stood appalled at times at the wonderful surgical feats accomplished by Nature, and yet she was a most bungling surgeon. As in all studies of medical problems, truth spelled itself out letter by letter, and a long time must elapse before a full knowledge of the subject was within our grasp.

The Library of the Surgeon-General.—Dr. A. Jacobi moved the adoption of the following resolution:

"*Whereas*, The library of the Surgeon-General's office in Washington, D. C., has for a long time needed additional shelving; and

"*Whereas*, Books are piled upon the floor and window sills, making it inconvenient and sometimes well-nigh impossible to find anything which is wanted, and greatly to the injury of the books; and

"*Whereas*, Estimates have been made from year to year for an appropriation to meet the cost of six iron book stacks; be it

"*Resolved*, By the New York Academy of Medicine, in its meeting of December 6, 1900, to petition the Congress of the United States to make the appropriation of $9,000 asked for for the above purpose, on the ground that without it the usefulness of the library of the Surgeon-General's office—the best-appointed library of the world, and the pride of the medical profession of all countries—will be seriously interrupted and crippled."

The resolution was carried unanimously.

War Tax on Charitable Institutions.—On motion of Dr. Jacobi the following resolution was also unanimously adopted:

"*Whereas*, In the session of 1898 the Congress of the United States has laid a war tax on legacies of charitable, educational, and religious institutions; and

"*Whereas*, The revenue from this and other war taxes has been unnecessarily large and in need of being reduced; and

"*Whereas*, The charitable and religious institutions of the country are seriously interfered with by the crippling of the income of organizations, almost exclusively derived from private sources; therefore, be it

"*Resolved*, By the New York Academy of Medicine, at its meeting of December 6, 1900, to petition the Congress of the United States to relieve charitable and religious institutions of the war tax hitherto levied, and to request every fellow of the Academy to inform our representatives in Congress of the reasons for such petition."

Inebriety in Russia.—The Russian minister of justice has transmitted to the commission appointed to reform the penal code a proposition emanating from the National Hygienic Society forcibly to detain confirmed inebriates in hospitals.

New Instruments.

A NEW INSTRUMENT FOR OPERATING ON CONGENITAL DISLOCATION OF THE HIP AND OTHER PATHOLOGICAL DISEASES OF BONE.

By A. M. PHELPS, A.M., M.D.,

NEW YORK.

THE orthopedic profession are pretty generally convinced that anything short of an operation of some kind in congenital dislocation of the hip will prove an absolute failure. Braces have been discarded, or if they have not been by some, they should be. It is little short of arrant charlatanism to humbug patients by applying braces. In congenital dislocation of the hip there are two reasons why braces are absolutely worthless.

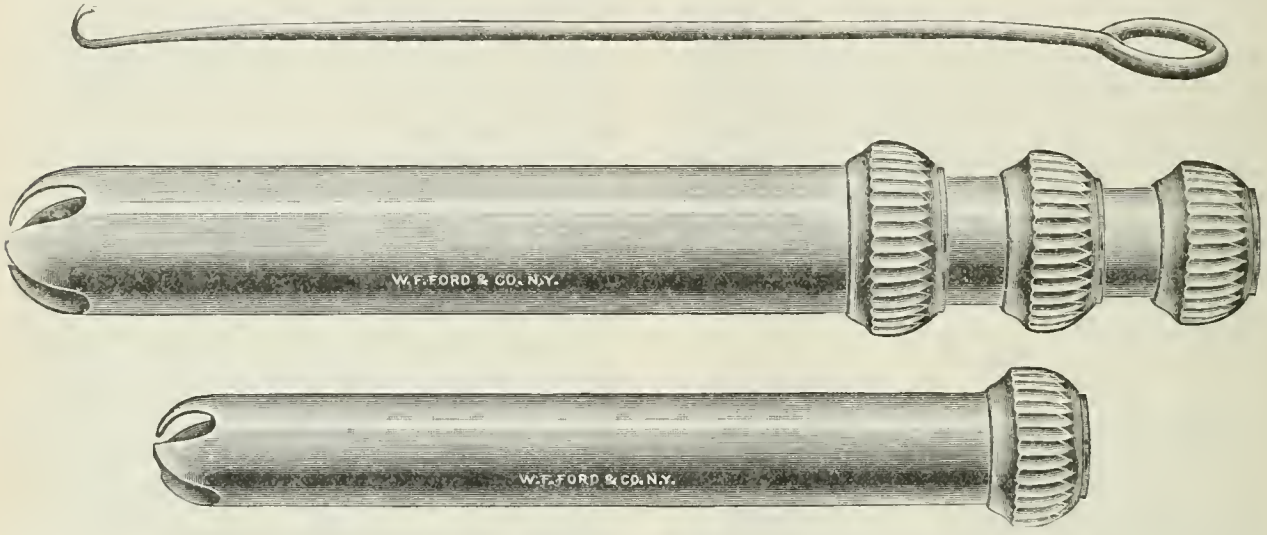
In the dissections which I published a few years ago, and in something like seventy-five cases of operations, I did not find an acetabulum in more than two or three of the cases into which it was possible to put the head of the bone and have it remain. It has been argued that pulling the limb down with the brace, and holding the head of the bone opposite the acetabulum would result in the head of the bone eventually grinding out a new socket. Clinical observation demonstrates this to be an error. All such cases relapse or are not benefited, and this has induced the profession to resort to some operative procedure for the relief of this deformity, which in the female results in distortion of the pelvis, endangering her life during the period of childbearing, so say nothing of the wobbling, shuffling gait in either sex which attends the displacement.

Hoffa's method of making a new acetabulum, and placing the head of the bone into it is one that has commended itself to me. Lorenz's method of "forcible replacement," as he calls it, is the twisting of the head of the bone around to a normal position, the soft parts holding the head of the bone against the acetabulum. This latter method I do not endorse, because in all of the cases which I have examined, with occasional exceptions, I have seen merely the posterior converted into an anterior dislocation, and the apparent benefit which is derived from it is that the anterior dislocation is attended with only one-half the shortening of the posterior. Then again, these cases I have observed as a rule are attended with continued increase in shortening. This is not always true, but it is altogether too common.

In Hoffa's operation an incision is made along the femur, beginning at the upper border of the acetabulum, and is carried down to the neck of the bone. This incision is a modification from Langenbeck's incision, which was advocated by Lorenz. The capsule is now detached from the interior trochanteric line two-thirds the distance around, and the head of the bone is then rotated out. The capsule is then split so as to admit the instrument, which was devised by Dijou, and it is one of the most useful I have ever yet seen. This instrument is a steel tube, ending with cutting edges on the curve to correspond to a perfect circle. It is on the principle of the old-fashioned pot auger. A few turns of this bores a hole into the pelvis, at the site of the rudimentary acetabulum, which perfectly fits the head of the bone.

As will be seen by the illustration there are three sizes, corresponding to the three sizes of heads that are usually found in such cases. The upper instrument is for the purpose of cleaning out the tube. After a few turns the bone which is removed from the pelvis will be found inside of the tube, and can be emptied out usually without the use of the hook.

Another application of this instrument is in excision of the hip. I find that the acetabulum can be cleaned out with it better than with the scoop, and frequently in children in whom the head of the bone is partially consolidated, after removing the great trochanter with this instrument, the neck and head of the bone and acetabulum can be bored out with very few turns, and the operation completed within two or three minutes.



I first saw Hoffa use the instrument in Kirmesson's clinic in Paris, and was so favorably impressed with it that I brought a set home, and have been operating at the Post-Graduate Hospital since my return, until I can commend the instrument to the profession without any qualification. In bone surgery it is better than the scoop. I can think of a great many operations upon bone in which chisel and scoop have hitherto been employed, when this instrument will do the work much more quickly and easily, and with less shock to the patient. The wound which is made by this boring instrument is perfectly smooth, with no ragged pieces of bone hanging to the soft parts, and no débris left in the wound.

62 EAST THIRTY-FOURTH STREET.

Quarantine Barges for Cuba and Porto Rico.—The steamship *Orion* sailed from Philadelphia on November 27th for Cuba, having in tow two disinfecting barges, the *Guardian* and the *Sentinel*, the former to be put in service at Matanzas and the other at Cienfuegos. The barges were converted from schooners. Another barge, the *Defender*, is being equipped at Philadelphia for quarantine work in Porto Rico.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending December 8, 1900:

	Cases.	Deaths.
Tuberculosis	246	134
Typhoid fever	110	21
Scarlet fever	144	3
Measles	63	4
Diphtheria	292	40
Laryngeal diphtheria (croup)	27	7
Cerebro-spinal meningitis	0	4
Varicella	66	0
Smallpox	12	3

No Plague Serum in Melbourne. — When the plague came to Melbourne a millionaire wool exporter sent for his doctor post-haste to inoculate him and his family. The doctor sent word he had no serum. "Get some," wired the millionaire. The doctor did his best, but failed. The millionaire, who was horribly nervous about infection, wired again, saying: "Get it at any price." The doctor offered $5,000 for a single syringe full of the culture; but all in vain. It appeared that a quantity of gelatin culture full of bubonic germs had been sent over from India some time before, but the authorities objected to it being landed. Taking advantage of the fact that gelatin was liable to duty, they confiscated and burned it.—*Answers.*

Abnormalities of Vaccination.—Dr. C. D. Smith, president of the State board of health of Maine, has published in the eleventh report of that body a valuable and exhaustive paper upon vaccination and vaccine lymph. Referring to the abnormalities of vaccination, and more especially to the eruption commonly known as "vaccinia," Dr. Smith says: "In the French classifications mention is made of a generalized vesicular eruption known as vaccine généralisée, due to blood infection. In this country it has been common practice, with a disregard of any systematic study of the points of difference, to speak of any general eruption associated with vaccination as 'vaccinia.' That this is incorrect must be apparent, from a review of the painstaking studies of our English and French confrères. I do not wish to do more than outline as briefly as may be the facts with reference to the characteristics of a true 'vaccinia,' or, more properly speaking, vaccinal eruption, due to the introduction into the blood of the specific vaccine virus. It appears in two forms: spontaneous when due to the absorption into the general circulation of the active principle of vaccine lymph. This is noted as a very rare affection; its tendency being to remain localized. It apparently results from the fact that the lymph loses its fixed character, and the organisms instead of following the rule seen in normal vaccination and producing their peculiar phenomena in a localized area, are diffused. It is confined almost wholly, though not invariably, to infants or young children. It may appear with the vesicles or later. When the infection results from taking the virus into the alimentary canal, as by sucking, the period of incubation is from four to eight days and the symptoms and eruption appear identical with true variola. Sometimes the secondary vesicles appear at the same time as those on the vaccinated arm and follow the same time of development. When the symptoms appear suddenly, there is marked fever, and the appearance in the areola of papules developing in two or three days into vesicles, being most closely grouped in the centre, often confluent, and becoming fewer and smaller and less markedly developed toward the periphery. At once, or soon after, there appear in other areas of the body, isolated, or in irregularly disposed patches, similar papules having the same shotty feel as in smallpox. These have an affinity for weak places in the skin (near original mark), and when occurring on the extremities select the flexor surfaces. The vesicles become scabs in a fortnight or a little more, sometimes in severer cases extending over three weeks and are not followed by pits, nor does the eruption attack the mucous surfaces. The other form due to auto-inoculation is less rare, and is usually accompanied by some cutaneous affection, such as eczema, erythema, or one of the papulo-vesicular eruptions. It occurs from the third to the eighteenth day after vaccination; it is conveyed from one to another part of the body by scratching and, as might be supposed from its mode of transference, frequently exhibits much inflammatory action and ulceration. There is no typical mark when the vesicles terminate without septic complications, and their duration is the same as in the spontaneous form. The chief interest in these two forms of eruption lies in their complication of a diagnosis during the prevalence of smallpox. From varicella they are to be distinguished by the larger size of vesicle; their irregularities of shape, and the fact of vaccination, and the length of time elapsing before their appearance, and the absence of any regularity or order of appearance. In variola the vesicles are as a rule equal in size. The clinical features are, with rare exceptions, uniform, and they are evenly distributed. Rarely in variola or varioloid are lesions absent from the mouth or pharynx." Dr. Smith wisely says that when in doubt between this eruption and varioloid, isolate promptly.

Wearing Out the Brain.—A French investigator has come to the conclusion that the brains of military and naval men give out most quickly. He states that out of every 100,000 men of the army or naval professions 199 are hopeless lunatics. Of the so-called liberal professions, artists are the first to succumb to the brain strain, next the lawyers, followed at some distance by doctors, clergy, literary men, and civil servants. Striking an average of this group, 177 go mad to each 100,000. Domestic servants and laborers are not far behind, the professional men supply 155 out of each 100,000 as candidates for the lunatic asylum. Next, but with a long interval, come the mechanics, of whom only 66 in each 100,000 lose their wits. Wonderful to relate, commercial men retain their sanity the best of the whole group, as they send only 42 out of 100,000 to the madhouse. The French scientist may be right, and doubtless he is so far as France is concerned, but in the United States we are convinced the order would be different. Doctors as a class would take a higher rank and the commercial men of this country go mad more frequently than the "hewers of wood and drawers of water." It is not complimentary to the business men to put them in a lower category than the ordinary day laborer. To become insane in itself is a presumption that one possesses brains, often indeed above the common. "Great wits are oft to madness close allied." Will some enthusiastic gatherer of statistics endeavor to clear this matter up?

Microbe Lamps.—An English weekly journal contains the following: "That some microbes can produce a bright light is the discovery of a French scientist. The newly found microbes have been named photobacteria, and with them a living lamp has been manufactured. The minute creatures are so small that

two hundred and fifty million of them could find standing room on a postage stamp, and the number required to produce a light bright enough to read by reaches a few thousand billions. The microbe lamp is merely a glass bottle containing water in which the bacteria have been cultivated. In a dark room the bottle glows like a frosted electric lamp, and gives a light strong enough to enable fine print to be read at a distance of five or six feet. The light is perfectly steady, and when the microbes can be cultivated on a large scale it is calculated that the cost will be about one halfpenny [one cent] per two hundred hours. The microbe lamps would not be renewed when the light diminished, but would simply be replaced by new ones, half a dozen of which could be carried in the pocket ready for use at any time; and as the bottles are sealed, the lamps are perfectly harmless. The light is continuous day and night, and only goes out when the microbes die." It is proposed, we believe, to light Paris and a few other French towns by means of these microbes, that is to say, if a sufficient number of the right sort can be found. Wonderful are the discoveries in the bacteriological laboratories!

The Use of Tobacco on Active Service.—*The Lancet* of November 10th says that "the war in South Africa has taught many things of greater and of less importance. Perhaps nothing that it has demonstrated has been more marked than the important part which tobacco plays in the soldier's existence. Whether this is to be reckoned as a great fact or a small one, there can be no doubt about the truth of it. Yet the Duke of Wellington's armies had no tobacco worth speaking of. If they did not forbid its use, at any rate the Iron Duke's officers were directed to advise their men strongly against it. What a curious contrast with the campaigning in South Africa, where marches and privations as long and as stern as any suffered by our great-grandfathers were borne by the volunteers and soldiers of to-day with a grumble only when their 'smokes' failed them. We have it from many who took part in the forced marches leading to Paardeberg, to Bloemfontein, to Pretoria, and beyond that, when rations were but two or three biscuits a day, the only real physical content of each twenty-four hours came with the pipe smoked by the smouldering embers of a camp fire. This pipe eased the way to sleep that might otherwise have lingered, delayed by the sheer bodily fatigue and mental restlessness caused by prolonged and monotonous exertion. It is difficult then to believe that tobacco is anything but a real help to men who are suffering long labors and receiving little food, and probably the way in which it helps is by quieting cerebration—for no one doubts its sedative qualities—and thus allowing more easily sleep which is so all-important when semi-starvation has to be endured. The cases of acute mental derangement in the course of campaigns such as the present are many. There have, indeed, been many in South Africa. It would be most profitable and interesting could medical officers have taken special note of the capacity for sleep previously evidenced by those who broke down and also of their indulgence or non-indulgence in tobacco. We are inclined to believe that used with due moderation tobacco is of value second only to food itself when long privations and exertions are to be endured. Two features are to be noted with regard to the smoking practised on active service. It is almost entirely in the open air and is largely on an empty stomach. The former is always an advantage, the latter we generally reckon a most unfavorable condition. Shall we see in the near future patients with tobacco amblyopia or smoker's heart acquired while the trusting friend of tobacco thought that he was enjoying the well-earned solace of a hard day's march? We believe not—and that the open air will have saved what might have been the untoward results of smoking when unfed." The most suggestive part of this instructive article is that which refers to the cases of mental derangement in the course of campaigns and their connection, if any, with smoking. Insanity has been considerable among our soldiers in the Philippines, and the surgeons there might with advantage investigate the question raised by *The Lancet* writer as to the capacity for sleep previously evidenced by those who broke down and also of their indulgence or non-indulgence in tobacco.

Diseases of the Philippine Islands.—Medical Inspector Remus C. Persons, U. S. A., writing in the report of the surgeon-general of the United States navy on the above subject, says: "The prevailing diseases are of the various types of fevers; of rheumatism, dysentery, and diarrhœa, of heat exposure, skin disorders, smallpox, beriberi, plague, and other diseases which are common everywhere, including the ever-present venereal troubles and alcoholic addiction. Dengue and thermic, malarial and typhoid fevers exist throughout the group of islands; nor is it to be wondered at, since no attempt at sanitation has been made outside of the Spanish-dwelling cities. Few places have water supplies or sewerage of any kind. The water-closet system is practically unknown, cesspools or privies above ground being the rule, and in native towns anywhere that is convenient. Most of the coast towns lie so low that but an imperfect system of drainage is practicable at the best. . . . The mortality has been about the same as at other plague infected centres. It has been diligently fought, both at Manila and Cavite. In Cavite the houses are also built with the lower story on the ground, in which many people are huddled, and it was among them the cases occurred, all fatal. There have not been any cases among the whites. The plague has not become epidemic, but the recognized cases have been so widespread as to lead to a belief that it is endemic, and that conditions have not become ripe for its becoming epidemic in the islands. All through the towns and in the country fevers of all kinds exist. A severe type of dengue is common, and in Cavite very few escape it. Fortunately it does not prove fatal, although it is often very distressing. There malarial fever is uncommon. There are no pools of stagnant water in which mosquitos can breed, and when it appears the plasmodium is evidently imported. In many sections of the lower islands it exists at its worst, and often proves quickly fatal. Smallpox is so widely spread as to be little regarded, and in some parts is considered by the natives as an almost necessary disease of childhood, and no attempt is made to keep it from spreading. A vaccine farm has been established in Manila, affording excellent virus from the native carabao, and compulsory vaccination has been established in Manila and many of the captured towns, and it is hoped to check its further spread, but it will require time to immunize eight or ten million people. Rheumatism stubbornly resists treatment, and relapses are common, and when once the disease obtains a good foothold the subject's usefulness is gone, and he should be given a change of climate. Diarrhœas from many causes are common but quickly yield to suitable treatment. Dysenteries, on the other hand, may be either quickly fatal or run into a chronic condition. The latter is of the amœbic variety, and though sometimes fatal, its tendency is to run into the chronic form when not promptly cured. The acute and generally fatal form is due to a specific bacillus. It is not as common as the amœbic form, which is fortunate, for it is very sudden and overwhelming in its action, and may prove fatal in three days. Beriberi is one of the

common diseases of the natives and most often proves fatal, if its ravages among the Filipino prisoners held in Cavite are not exceptional, where the fatality was so great, notwithstanding treatment by Filipino physicians, that the rest were liberated to prevent the further spread. Venereal troubles abound as elsewhere, but show no special virulence. Fever after exposure to the sun often occurs. . . . There are many insect pests on shore, as mosquitos and the different forms of itch. It is not known whether or not the former are malaria breeding, but it is certain they are voracious and poisonous. The 'dhobie' or washerman's itch finds its way on shipboard and is quite common and annoying, but the insect is easily killed. The variety known as sama makes deep and excessively painful sores, which are hard to heal."

The Mosquito Family.—The word mosquito has no scientific import. Derived from the Spanish or Portuguese, it simply means "little fly"; it is used popularly to denote a gnat which bites, and most gnats bite when they have a chance. The word is sometimes extended to include certain midges. The Dipterous family Culicidæ, to which the gnat belongs, contains, according to Major Giles, some two hundred and forty-two species divided among eight genera. The great majority of species (some one hundred and sixty), however, belong to the genus Culex; Anopheles includes thirty, while the remainder are divided among the other six genera, none of which are large. The collections which have recently been made at the British Museum are said to contain ten species of Anopheles new to science, so that if all Major Giles' species are accepted we have a total of some forty species of the genus which has been hopelessly convicted of being the medium by which the malaria parasite is transmitted from person to person.—*Quarterly Review.*

Anti-Plague Inoculation.—Professor Calmette, of the Pasteur Institute at Lille, who has made a special study of the bubonic plague, was requested by the College of Physicians and Surgeons of England to deliver the second of the Harben lectures. The subject selected was anti-plague serum therapy. Dr. Calmette said: "In all cases the infection, whatever the mode of entry of the virus, resulted in the multiplication of the plague bacillus, first in the lymphatic channel and then in the blood. Even a few hours after infection the bacilli were to be found in the blood, and they existed in immense quantities in all the organs of the person attacked. The effect, therefore, of an injection of the serum should be to provoke their rapid destruction by phagocytosis and bacteriolysis. But this result was scarcely attained by the slow absorption of serum injected subcutaneously. The organism not being at once impregnated with the active substance, some of the bacilli escaped the phagocytic process, and growing accustomed to the action of the serum this was powerless to check it. This explanation of the non-success of the sero-therapic treatment was confirmed by clinical observation. But the results were different if the serum, instead of being introduced merely below the skin, was as soon as possible after the beginning of the disease injected straight into the veins. Four or five hours after such injection the temperature dropped, rising again for eight or twelve hours afterward, and then dropping finally. This temporary drop corresponded to the period during which the bacilli were being removed from the circulation by the leucocytes. If the treatment had been speedy, cure was effected in two or three days. The serums of vaccinated animals contained two substances—one alexin, which had the power of digesting the bacterial cell and which existed in normal serums, and the other the reagent or intermediary substance, which existed only in very small quantities in normal serums. In unvaccinated animals, as the reacting substance did not exist in sufficient amount, the normal alexins in the blood were unable to dissolve the microbic bodies when serious infection took place. Hence to overcome the infection a sufficient quantity of the reacting substance must be supplied to the organism. Anti-plague serum was a reacting substance, and within its sphere of action when infected the leucocytes and alexins were unable to dissolve the plague bacilli; though beyond it the bacilli escaping phagocytosis gradually became immune. Hence it was necessary that the reaction of the leucocytes and alexins should be carried on simultaneously through the organism, and as rapidly as possible, and hence the reason why the serum must be injected into the general circulation. A very small quantity of the serum was sufficient to react on an enormous quantity of alexin."

Entries at the English Medical Schools.—Several of the English medical papers have alluded with pleasure to the fact that the entries at the various medical schools show a decided falling off this year. In London this is especially marked, as the following figures will show: For the full course there are less students entered to the extent of 28 at St. Bartholomew, 12 at St. Thomas, 10 at St. George, 9 at the London, 8 at Charing Cross, 7 at St. Mary, and 1 at University College. In the provincial schools the decrease is said to be as follows: Owen's College, Manchester, 29, Liverpool 18, Bristol 10, Durham University 7. The schools showing an increase are London School of Medicine for Women 5, King's College 4, Guy's 5. At Leeds the increase is 12, Sheffield 3, London School of Tropical Medicine 4, and London School of Dental Surgery 10. Altogether the net decrease up to date amounts to 102. The cause for this condition of affairs, which must be termed satisfactory, is twofold: First, parents now recognize that the expense of putting a young man through his medical course does not meet with an adequate return; and, secondly, now that the curriculum is lengthened to five years, and that the examinations are more severe, many youthful aspirants to a medical degree are daunted by a fear of failure. If some such system could be introduced into this country it might be for the good of all concerned.

The Twentieth Century Baby.—The baby of today bids fair to replace the crush of ancient creeds and the wreck of superstitions that have been everywhere undermined by the ruthless hand of modern science. For its behoof many books are written, many carriages are constructed, many foods are invented, many garments, many toys, and many medicines are advertised. As a matter of sober fact, it is threatened with manifold drawbacks to development, short of actual extinction, by the wholesale substitution of the artificial for the natural. Instead of the most perfect food in nature, mother's milk, we find a host of artificial substitutes, each one of them, if we may trust the proprietary representations, calculated to rear an infant with the brains of a Newton combined with the frame of a Samson. How often, alas! the outcome of all these costly cares is a being of stinted body and limited intellect, unfitted to play a soldier's part in the battle of life. This question of food strikes deep into the physical welfare of a race, and there can hardly be a more serious national problem than how to rear this twentieth-century baby of ours in strength and happiness. There is a vast deal of nonsense written and taught about the proper way to clothe, nurture, and tend babies generally. The best basis is that of plain milk diet, either from the breast or from modified cow's milk. For the rest, those ills that are preventa-

ble should be prevented. Most of the mischief done in the nursery is the result of attempting to do too much. It would be an important step toward the stability and future of our race were the laws of health to be taught in our schools, with a special class on nursery management for the girls' classes.—*Medical Press.*

Tuberculous Milk.—Professor Delépine, in the section of preventive medicine at the late annual congress of the British Sanitary Institute, read a paper on the above subject, the gist of which is contained in the following: "It was known that tuberculous cows did not yield tuberculous milk when their udders were healthy. Exception might be taken to this statement on the ground that a few cases of tuberculous cows with reputed healthy udders had been reported in which the milk was found to contain tubercle bacilli. Such cases might occur, but must be rare, and he had examined many udders from cows which had given tuberculous milk and had not yet found a single cow in which the udder was healthy. . . . Notwithstanding an experience of some seventeen years, he felt still unable to place much confidence in the negative results of microscopical examination. . . . The practical conclusion was evident that sanitary authorities would not be able to stop very rapidly and completely the sale of tuberculous milk. It was therefore necessary that the public should be reminded again and again that they must boil all milk which they consumed, and more especially that which was supplied to infants."—*Medical Magazine.*

Is the Anglo-Saxon Race Degenerating?—Dr. James Russell, of Hamilton, Ont., read a paper on the above subject before the American Psychological Association, in which he ascribed the decadence of the Anglo-Saxon race to the dearth of good literature. The pith of Dr. Russell's remarks was as follows: "Nowadays men have no time for reading except for recreation or business demands. They scan the morning newspaper for the war news, the stock exchange reports, or the latest horse race or prize fight. The gambling spirit is dominant everywhere, and is not confined to one sex. There is no time for deep reading or profound thinking. The mad struggle is after wealth. Literary barrenness is the consequence, and the tendency is everywhere to superficial thinking, with a little knowledge of everything. There are no great living poets, philosophers, or divines whom the masses are looking to for guidance. They are not forthcoming because there is no demand for them. The mind of the age is focussed on one great, paramount idea—the acquisition of wealth. The human brain is a composite organ and susceptible of enormous expansion and development, but like everything human it has its limitations. Whether or not it can stand the enormous strain of the present rate of activity and continue to project itself with unabated vigor into the future, is the great problem now before us for discussion. If we are to be guided by the history of the past we must answer in the negative."

Smollett on Surgeons.—It has been customary of late to quote Smollett's "Roderick Random" as affording a perhaps complete picture of the state of the profession of surgery in England in the age preceding that of John Hunter. Roderick Random, it will be remembered, was examined at Surgeon's Hall in the Old Bailey, where he was twitted, mulcted, and browbeaten by a group of examiners who were certainly a dishonor to their profession. A plump gentleman, it is true, asked him to describe "the operation of the trepan" in such a sensible manner that Roderick was able to give a sensible answer, but the next examiner was a wag. "If," said he, "during an engagement at sea a man should be brought to you with his head shot off, how would you behave?" The next examiner with a pert air asked Random, who of course was Smollett himself, "what method of cure he would follow in wounds of the intestines?" Then followed a pretty altercation between the plump gentleman, who had authority for supposing that such wounds are curable, and the examiner, who affirmed all wounds of the intestines, whether great or small, to be incurable. "Sir, excuse me," interrupted the irate examiner, "I despise all authority *nullius in verbo;* I stand on my own bottom." "But sir, sir," replied his antagonist, "the reason of the thing shows——" "A fig for reason!" cried this sufficient member; "I laugh at reason; give me ocular demonstration." A grand quarrel now ensued, and Smollett was ordered out of the room, only to be recalled to receive his sealed qualification and to pay his fee. He laid down a long-hoarded half-guinea on the table and waited for change, the fee being five shillings. The examiners were once more unanimous; one of them bade him begone. "I will," said Random, "when I have got my change." Thereupon another examiner threw him his five shillings and sixpence, remarking, "I should not be a true Scotsman if I went away without my change."—*English Medical Review of Reviews.*

Health Reports.—The following cases of smallpox, yellow fever, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended December 8, 1900:

		Cases.	Deaths.
Smallpox—United States.			
District of Columbia Washington	November 12th to 24th	3	
Kansas, Wichita	November 17th to December 1st	10	
Kentucky, Lexington	November 17th to December 1st	3	
Illinois, Cairo	November 27th	1	
Minnesota, Duluth	November 8th to 22d	54	
Minneapolis	November 24th to December 1st	1	
St. Paul	November 8th to 22d	2	
Winona	November 24th to December 1st	60	
Counties, Carlton, Hennepin, Kandiyohi, Le Sueur, Lyon, Meeker, Pine, Ramsey, Wright	November 8th to 22d	73	
Missouri, St. Louis	November 23d to December 3d	3	
New York, New York	November 24th to December 1st	34	
Ohio, Ashtabula	November 24th to December 1st	7	
Cleveland	November 24th to December 1st	34	1
Pennsylvania, Alleghany	November 24th to December 1st	1	
South Carolina, Greenville	November 24th to December 1st	3	
Tennessee, Nashville	November 24th to December 1st	1	
Texas, Blue Springs	November 22d	Present.	
Sublime	November 22d	14	
Vashti	November 22d	Present.	
Virginia, Alexandria Co	December 5th	1	
W. Virginia, Harrison Co	November 28th	18	
Wheeling	November 24th to December 1st	2	
Smallpox—Foreign.			
Austria, Prague	November 10th to 17th	29	
Ecuador, Guayaquil	October 6th to November 17th	..	40
Egypt, Cairo	November 3d to 11th	..	1
France, Paris	November 10th to 17th	..	15
Gibraltar	November 3d to 11th	1	
Greece, Athens	November 10th to 17th	2	1

ON A CASE WHICH ILLUSTRATED CONSERVATISM IN SURGERY.
THE LIABILITY OF AN ANCIENT CICATRIX TO CANCEROUS DEGENERATION.
A NEW METHOD OF AMPUTATION AT THE KNEE WHEN THE ARTERIAL CIRCULATION OF THAT REGION IS IMPAIRED.

BEING THE ABSTRACT OF A LECTURE DELIVERED IN BELLEVUE HOSPITAL, JANUARY, 1900.

BY STEPHEN SMITH, M.D., LL.D.,
CONSULTING SURGEON.

THIS patient gives a history which recalls conservatism in surgery half a century ago and also illustrates the liability of an old cicatrix to cancerous degeneration. In the treatment of the conditions existing in the limb at present I shall take occasion to demonstrate a method of amputation at the knee which has proved successful in similar cases in which the arterial circulation in this region has been impaired.

For the early history of the case I must rely upon the patient himself chiefly, though I have a recollection of its principal features. Michael R—— is now between sixty and seventy years of age. He came to this country as a young man, and engaged in business as a stone-cutter. Without other assignable cause than the accidents incident to his trade he developed either an acute periostitis or an osteomyelitis of the right tibia, which resulted in the death of the entire shaft of that bone. He states that after a long period of suffering he entered the New York Hospital, then located at Duane Street in Broadway. The leg was greatly enlarged and from numerous openings pus was constantly flowing in large quantities. He was in feeble condition, and his irregular chills and night sweats indicated that he was suffering from septicæmia if not pyæmia. A consultation was held, and the unanimous opinion was that amputation must be immediately performed to save his life. Looking backward to the personnel of the staff of visiting surgeons of that hospital forty years ago we recognize that the consultation was notable for the character of the surgeons composing it. Dr. Valentine Mott ranked among the most eminent of living surgeons; Dr. Alfred C. Post was noted for his precision, Dr. Gurdon Buck for his conservatism, Dr. John Watson for his learning. It is quite certain that Ryan's case was thoroughly examined in all its aspects, for a consultation in those days was no mere formal affair, but an occasion for the most critical comparison of the learning, skill, and experience of the consultants. R—— promptly rejected the conclusion of the consultation, and determined that his body and leg must not be separated. He was accordingly discharged from the hospital for refusing treatment, and soon after entered Bellevue Hospital. At that time Bellevue was passing through the preliminary stages of conversion from the *régime* of an almshouse to that of a well-organized hospital, and was beginning to attract the attention of students engaged in clinical studies. The New York and Bellevue hospitals were then the only hospitals in the city, and though the former had long been the favorite resort of medical students owing to its age, the reputation of its medical staff, and the number of operations which were performed, the latter had the advantage of a greater number of patients and of location. Its surgical staff was composed of young surgeons who were very ambitious to render it as attractive as possible to students. To this end they sought to multiply those conditions most likely to secure a large attendance, the most important of which always proves to be a large supply of operable cases. R——'s advent and the report that he had refused amputation at the New York Hospital and thus secured it to Bellevue were regarded as happy auguries for the future of the latter hospital.

It is quite impossible for the surgical student of today to realize how limited was the field of operative surgery fifty years ago. Then an amputation was a capital operation and when advertised to occur in the New York or Bellevue Hospital, it attracted crowds of eager students and practitioners. Now amputations are for the most part relegated to the house staff and the attending surgeon interests himself in new and curious vivisections which tend more and more to bring human ills within the domain of practical surgery. You may witness durin a winter session in the thirty or more hospitals of the city scores and scores of operations of which the surgeons who consulted in the case before us had not the remotest conception.

R—— informs us that on entering Bellevue he was assigned to the wards of Dr. James R. Wood. Dr. Wood was one of the leading surgeons of the city and was especially skilled as an operator. He concurred in the decision of the consultants of the New York Hospital that amputation offered the only chance of saving the life of the patient. R—— stubbornly refused to submit and was in turn discharged from Bellevue for refusing to submit to treatment. At that time I was the junior surgeon of the visiting staff and, as was the custom of the recent graduates of that period, was engaged in teaching private classes and in giving them clinical instruction at the bedside in the wards —true clinical teaching. R—— states that while he was in Bellevue I visited a patient near him who was suffering from a disease of the arm which involved the question of amputation. He overheard me remark to the students, "I should regard it more creditable to save one arm than to amputate a dozen." This statement greatly impressed him and he at once determined to return to the hospital after his discharge, and obtain admission to my wards. He carried out his purpose and entered my service. It appears that on examination I proposed to make an exploratory operation. At the general consultation which followed, the leg was condemned to amputation by all of the surgeons, but, as was the custom, when the surgeon-in-charge proposed tentative measures he was allowed to employ them at his discretion. At the last moment before taking the anæsthetic R—— directed me to amputate the limb if I believed, on exploration, that it could not be saved. The first steps in the operation revealed necrosis of the entire shaft of the tibia and a large, well-organized involucrum. This ensheathing

bone was laid open the whole length of the tibia, the dead shaft was divided in the centre, and the separate portions were removed. The recovery was rapid and complete. For thirty years R—— pursued his trade actively—making and losing a fortune during that time. Within the last few years the cicatrix at its upper extremity has opened and allowed the escape of small fragments of necrosed bone, but he suffered no inconvenience from the discharge until a year or more ago when the opening began to enlarge and show no tendency to heal as formerly. He then came under my observation again and on microscopical examination of sections of the surrounding parts of the ulcerating wound it was found that the granulation tissue was cancerous. It was now apparent that we had to deal with a new condition. Cancer had developed in the ancient cicatrix. Prolonged efforts were made to destroy the new growth but, while the external surfaces assumed a healthy appearance and partially healed, the disease penetrated the bone and, finally, the shaft separated. Amputation is, of course, now the only remedy, and it is an interesting circumstance that, after actively using the once condemned limb nearly a third of a century, R—— returns to me with the request and determination that I shall perform the operation originally proposed at two hospitals, but strenuously rejected by him.

The only interest which attaches to his previous history is as to the position of conservatism in the practice of surgery forty years ago. The amputation of a leg in the condition of R——'s was regarded preferable to the removal of the necrosed shaft of the tibia because it was believed to be the safer procedure. Only the student personally familiar with the practice in one of these great hospitals prior to the introduction of antiseptics can appreciate the line of reasoning which led that able body of consultants to what now seems a strange and inconsistent conclusion. I can vividly recall the morning and evening rounds, while a member of the resident staff of this hospital, with pus basin or pail in hand; the offensive dressings that had to be removed; the screams of suffering patients; the cadaveric faces of those recently operated upon, now slowly passing into the septicæmic or pyæmic state. The consultants reasoned, as I recollect, in this way: "R—— is slowly failing on account of the extensive suppuration in his leg; this suppuration will be greatly increased by the large wound necessary to remove the dead bone; he will not survive any additional exhaustion. If, however, an amputation is performed and this suppurating mass removed, thus substituting a fresh and comparatively small wound which may quickly heal, his chances of recovery will be greatly improved." They reasoned correctly from their premises that the real danger to this patient, as in all surgical cases at that time, was suppuration, and amputation was the only method of relief from this fatal complication. In our time the question of the dangers of suppuration would not have been mentioned in the consultation.

The second interesting feature of this case is the appearance of cancer in an ancient cicatrix. This is by no means an unusual occurrence and is quite in accord with the known histology of this disease. Cancer always represents degeneracy of tissues, and hence is far more frequent at the period of life when all the structures of the body are undergoing degenerative changes, indicated by diminished vitality. For the same reason cancer appears by preference in tissues of low vitality, whether from old age or from their inherent structure. A cicatrix always has a low vitality and belongs to the degenerate tissues from the very nature of its organization. In the case of R—— we have both conditions, viz., old age and a lowly organized tissue. The development of cancer, therefore, in this cicatrix was to have been expected rather than to have caused surprise.

The treatment is clear and unmistakable. There can be no question now as to the propriety of an amputation. This is the only alternative left us. The real question is, Where shall be the point of election? We have the knee and the thigh to select from, and as between the two we should select the place which will most certainly protect the patient from a recurrence of the disease and give a stump best adapted for an artificial limb. Fortunately amputation at the knee answers affirmatively both indications. I purpose, therefore, to amputate at that point. But owing to the extensive cicatrix around the joint the flaps are so poorly nourished that there will be great danger of sloughing if the amputation is performed by the usual method of making a hood-like covering for the stump. I shall, therefore, adopt a procedure which I devised in a case of senile gangrene due to extensive atheroma of the arteries. As this operation is, I believe, new and well adapted to feeble or impaired circulation at the knee it may prove useful to you hereafter if I give the details of the original case and the reasons which led to the new procedure, together with the several steps of the operation.

The patient was a laborer, seventy-eight years old and much addicted to the use of whiskey. He had been suffering upward of a month with gangrene of the great toe of the right foot. He was greatly emaciated, had no appetite, was extremely feeble, and complained of the excessive pain in his toe which prevented sleep. On examination his arteries were everywhere rigid with calcification and the heart's action was very feeble and intermittent. The urine was of low specific gravity and a small amount of albumin was found, but there were no evidences of sugar. The toe was black to the second joint and dry, but there was some swelling of the foot and dusky spots were noticed on its dorsum and on the leg above the ankle. The capillary circulation was very feeble, as appeared on pressure at different points of the leg.

In his enfeebled condition the only treatment possible was directed to relieving his sufferings from pain in the affected toe and to nourishing him with the most digestible foods. To meet the first indication he was ordered the opium and soap pill, one grain of each, and one pill to be given three times daily. His diet was to be as much peptonized milk as he could be induced to take and two ounces of whiskey every six hours. As tonics he took gr. $\frac{1}{60}$ of strychnine three times daily, and $\overline{3}$ ss. of compound tincture of cinchona three times daily. Hot irrigations of weak solutions of carbolic acid were employed at intervals, and at other times cloths wet with a solution of the same material were applied. He soon began to show marked signs of improvement. With the abatement of pain he slept much of the time, while the whiskey and milk agreed perfectly with his previous habits. The heart's action improved, the pulse becoming full and regular. The gangrene slowly extended, the margins being moist while the extremity was black and mummified. He now began to be anxious to have more radical measures employed and was willing to submit to amputation provided he was liberally supplied with stimulants.

The question of amputation was again seriously discussed, and the point of interest was to determine the place of election. Surgeons have in these latter days been inclined to select the knee joint or some point in the lower part of the thigh as the safest place of amputation in cases of senile or dry gangrene of the toes, and by some this election is regarded as a departure from the rule governing the older surgeons. It is true, however, that the surgeons of half a century ago recognized the importance of amputating at a dis-

tance from the seat of gangrene and often selected a point of healthy tissue between the ankle and the knee joint. It is also true that several American surgeons preferred amputation at and above the knee joint for the same disease. Pitney, of Auburn, N. Y., advocated amputation above the knee joint in senile gangrene of the toes as early as 1837. Mott was accustomed to advise and frequently practised amputation above the knee in these cases. Parker, of New York, also gave careful instruction in his lectures as to the selection of a point above the knee for amputation in dry gangrene of the foot. More recently Mr. Jonathan Hutchinson, of London, published a paper read before the Medico-Chirurgical Society in which he advocated amputation above the knee in gangrene of the foot and reported several cases. He gives the credit of definitely proposing the operation to James, of Exeter, but it had been frequently performed both in this country and on the Continent before that date. The operation above the knee has attracted attention in Europe and Heidenhain, Kruger, and others have reported favorably upon it. In this country Powers, of Denver, has advocated the so-called high operation for gangrene of the toes in an interesting paper recently published.

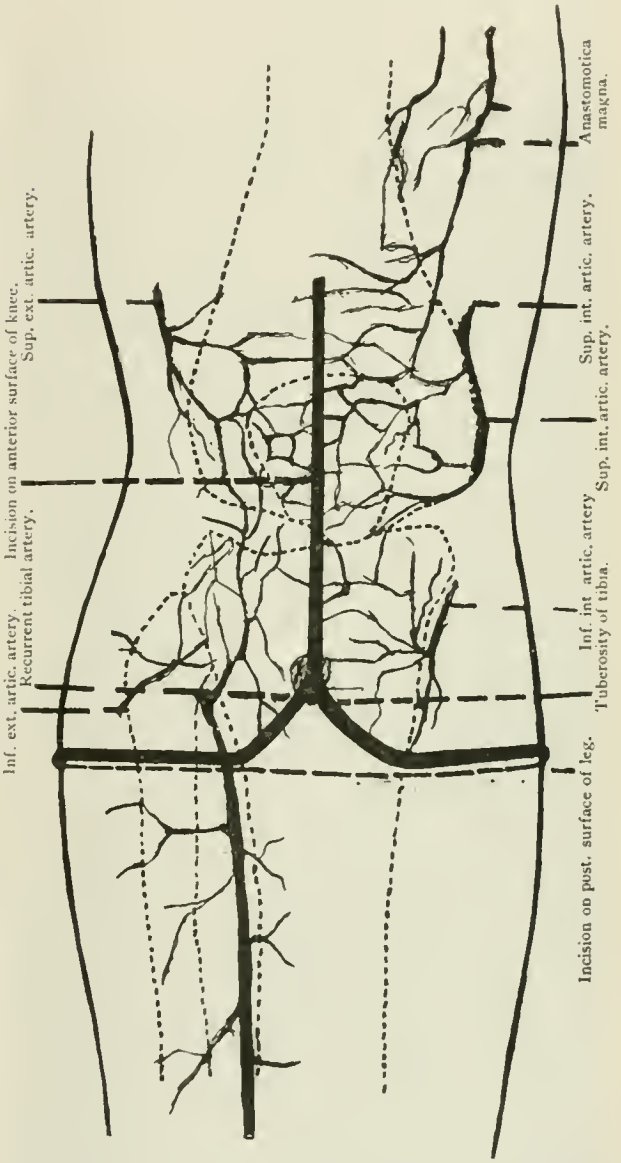
Those writers who have given their reasons for preferring the high operation allege that it is impossible to determine at what point the obstruction of the artery exists and that, as the operation must be above that obstruction, it is better, as a matter of safety, to be sure of healthy and well-nourished flaps by operating far above the limits of gangrene. In my case the condition of the arteries throughout the leg was most unfavorable to amputation at any point, for the capillary circulation was everywhere greatly impeded. The question was, therefore, Where under the circumstances can flaps be secured having an adequate blood supply to prevent mortification? It was apparent that amputation at or above the knee by any previous method would not meet the indications, for in each of these operations the arteries supplying the flaps are liable to be divided near their origins.

The question as to the best method of procedure in this case was decided by the following considerations: The structures about the knee are more largely and directly supplied by arterial blood than any other tissues of the leg. The arteries distributed to the knee are (see illustration) the four articular, the anastomotica magna, the recurrent tibial, the azygos, and the sural. If an amputation at the knee joint could be so performed as to save all these arteries at their origins it is evident that the flaps would have an immense supply of arterial blood. On reflection the following method of procedure was adopted:

Operation: Make a straight incision, commencing two inches above the upper border of the patella, downward over the centre of that bone to the tuberosity of the tibia; from the lower extremity of this incision make two curved incisions, the convexity of each being downward, one toward the external border and the other toward the internal border of the leg; now join these two incisions posteriorly by a straight incision across the upper border of the calf. Dissect these two flaps from the tibia and fibula, remove the patella, and disarticulate the tibia.

The advantage of the operation will be recognized on referring to the distribution of the arteries at the knee. It may be stated as follows: The straight incision on the anterior part of the knee, which opens the joint, divides only the terminal extremities of the articular arteries, thus preserving to the flaps the full amount of blood which they normally receive. In the other approved methods of amputating at the knee joint the dissection involves the division at their origins of several arteries supplying the flaps, by the straight incision on the posterior part of the leg or in the ham. Though the recurrent tibial is divided at its origin, yet its anastomosis with the articular arteries is preserved and thus the capillary circulation is well maintained at the extremity of the flaps. The precautions to be taken are these: the lateral incisions from the lower extremity of the perpendicular incision should curve well forward, the internal to secure an ample flap for the long internal condyle of the femur and the external to include the branches of the recurrent tibial artery.

As all the arteries of the leg were very brittle, neither the tourniquet nor Esmarch's bandage could



Anastomotica magna.

be safely applied, and the circulation was controlled by gentle pressure with the fingers on a large compress placed over the femoral in its first part.

The patient was prepared for the operation as I am accustomed to prepare the old or feeble who are liable to collapse during an operation from failure of the heart, by giving him one ounce of whiskey in four ounces of hot milk every two hours, commencing at 8 o'clock A.M. of the day of the operation. At 3 o'clock of that day his pulse was 96 per minute, full, regular, and slow; his respirations were 22 per minute; his mind was undisturbed, and he expressed himself as glad that the operation was to be performed. He required but little ether and passed through the operation without a struggle, his pulse remaining at 96, and respirations at 22 per minute. Primary union of the flaps followed, without an appearance of pus. It

was noticeable, on removal of pressure on the artery at the groin, that the flaps resumed a pink color, showing that the capillary circulation was fully and immediately restored. In due time the patient was supplied with an artificial limb which took direct bearing upon the extremity of the stump and he walked with scarcely a limp, using only a cane.

THE NEURON DOCTRINE: ITS PRESENT STATUS.[1]

By CHARLES LEWIS ALLEN, M.D.,

TRENTON, N. J.,

PATHOLOGIST AND ASSISTANT PHYSICIAN, NEW JERSEY STATE HOSPITAL AT TRENTON.

While the name is of comparatively recent origin, having been proposed by Waldeyer in 1891, the conception of the neuron is closely connected with the development of the idea of cell individuality. This, first brought forward by Schleiden in 1838, received a great impetus through the adoption of the cellular pathology of Virchow. Until the advent of Deiters in 1865, however, the relation of the nerve cell to the nerve fibre was involved in much confusion. Deiters first distinguished sharply between the two kinds of processes arising from the nerve cell, and confirmed the earlier observation of Wagner that but one of them was in direct relation with a nerve fibre, while all the other processes, separating themselves from their cell origin, divided and subdivided until they became lost in the ground substance of the nervous system. To the former of these processes he gave the name of axis cylinder; to the latter, that of protoplasmic processes, which names are still retained. As now generally understood, by the term neuron is meant the nerve cell and its processes, the biological unit of the nervous system.

While it is perhaps somewhat questionable just how far the term should be restricted, by the nerve cell is generally meant the mass of protoplasm, sharply outlined and provided with a nucleus, from which the two sets of processes arise.

Nerve cells differ enormously in size and shape, and their structure appears differently, depending upon the method of preparation of the specimen. Since the modern conception of the neuron had its origin very largely in the pictures furnished by the method of metallic impregnation, it will be well first to consider briefly the general appearance of the nerve cell and its processes as brought out by its use. This method, first proposed by Golgi in a number of communications published between 1871 and 1885, consists in a hardening and metallic impregnation by chromic salts with silver or mercury. It has been variously modified, and, in the hands of Golgi himself and of others, has furnished the most striking pictures. Among the numerous workers by this method is especially to be mentioned Santiago Ramon y Cajal, to whose untiring energy and to whose wonderful technique we owe so much of our modern knowledge of the nervous system. The method, however, while it gives a sharp and distinct silhouette picture, furnishes no information as to the internal constitution of the neuron. Again, while the cell body and the protoplasmic processes are brought out at any age, it is possible to trace out the axis cylinder only in the nervous system of very young or embryonic animals, since after its medullary sheath is acquired the axon is not reached by the metallic impregnation. When the coloring-process has been successfully carried out the nerve cells appear as solid black bodies without trace of structure, varying enormously in size and shape. The protoplasmic processes vary in appearance and in number in different cells, but, in a general way, after leaving the cell body they divide and subdivide much like the branches of a tree; hence they are also called dendrites or dendritic processes. Their final divisions form a close meshwork and do not anastomose, but end free.

Upon these processes there are small pyriform projections, the gemmulæ. The axis-cylinder process, or axon, may arise directly from the cell body or through the intermediary of a protoplasmic process. It may break up in the immediate neighborhood of the cell, or may pass along, giving off at intervals collaterals.

Both the original process and its collaterals terminate eventually in an end brush, which comes into close relationship with either the branched protoplasmic processes or with the cell body of another nerve unit. Here, then, we have the conceptions of a neuron: the nerve cell, its dendrites in close relationship to the end brushes of axis cylinders or collaterals of one or more other cells, is, by its own axon and collaterals, brought into relation with still other cells, either directly or through the protoplasmic processes of these last, connection thus existing from neuron to neuron throughout the nervous system.

Along the different neurons the nervous impulse is transmitted. For example, let us trace the course of the impulse from the brain cortex to the limb muscles. The large pyramidal cells of the motor region of the cortex are related through their dendrites with fibres from different sources. Excited to discharge, their impulse is transmitted along their axons through the centrum ovale, internal capsule, and brain axis; crosses to the opposite lateral pyramidal tract in the lower part of the medulla, and proceeds down the spinal cord—the central motor neuron. In the cord the axons give off collaterals, and eventually themselves pass forward to break up around the large motor cells in the anterior horns. These cells discharging send out an influence through their axons into the anterior roots of the spinal nerves, and thence to the muscles—the peripheral motor neuron. Impulses from the periphery travel by the posterior roots and spinal ganglia, to be transmitted either in the posterior columns to higher levels, or by fibres or collaterals which turn inward and pass to other neurons of the cord, some of them being transmitted via the peripheral motor neuron to the muscles, as in the common phenomena of the reflex. In a similar manner, an impulse may pass through a number of neurons. While the protoplasmic processes are usually sharply distinguished from the axis-cylinder processes in appearance, such is not always the case, and it may be difficult to tell one from the other.

The mass of evidence goes to show that, under normal conditions, the protoplasmic processes conduct only toward the axons away from the cell. As to whether the relation between adjacent neurons is one of continuity or of contiguity has always been disputed. Heretofore the evidence has been almost entirely in favor of the latter view. The end brushes of the axons and collaterals, and the finest ramifications of the protoplasmic processes, are intimately interlaced and closely applied one to another, but in no case has either the Golgi method or yet the vital methylene-blue method shown direct continuity between them from neuron to neuron. The results of some methods more recently applied will be considered later.

The gemmulæ of the protoplasmic processes have been thought to play an important rôle in bringing about the relations of contact. An interesting attempt has been made to account for certain psychical and other processes, notably for sleep and for hysterical

[1] Read before the Mercer County Medical Society, October 9, 1900.

paralyses, by assuming that the nerve cells are able to retract their processes, increasing and diminishing the size of their gemmulæ by a species of amœboid movement. This idea, which seems to have been based almost entirely upon theoretical grounds, has never been widely accepted, and is strongly opposed by the evidence of recent investigations. As stated above, the chrome-silver method gives no information as to the internal structure of the neuron.

The nerve cell was long ago studied by means of hæmatoxylin, carmin, and other stains, and its general shape and nucleated structure were made out, but our knowledge of its finer internal arrangement we owe almost entirely to the method of Nissl and its homologues. This method, preferably applied to paraffin sections, consists in staining by a solution of methylene blue and soap, decolorizing in aniline alcohol, dehydrating, clearing, and mounting. When properly applied, it shows the cell to consist of a colored and an uncolored portion. The stained portion, chromatophile substance, Nissl bodies, or tigroid is variously arranged in different cells, but consists in a general way of particles varying in size and shape, contained in the meshes of an unstained lattice work.

Within the last few years the study of the nerve cells in normal and pathological conditions by this method has occupied the attention of a large number of workers, and much information has been obtained about the changes subsequent to injuries of the axon in various diseases, and as an effect of poisons. Upon this subject alone extended monographs have appeared, and space does not permit entering upon it here. Suffice it to say that the changes observed have been mainly those of disappearance or of alteration of the Nissl bodies—a chromatolysis, and displacement of the nucleus.

The chromatophile substance extends to some extent into the processes of the cell, but it is impossible by this method to trace these for any distance. The consensus of opinion at the present time seems to point to the unstained portion as the functionally active part of the cell. By the finer methods the axon is shown to have a fibrillated structure. The apparent method of conduction of nervous impulses has already been discussed. Besides this, the nerve cell, as is well known to all, appears to exert a trophic influence, not only over its own processes, but over muscles and other structures to which its axon extends. It was shown long ago by Waller, that when a nerve was cut the part separated from its cell of origin degenerated. Now, besides this Wallerian degeneration, it is now known that the central portion of a cut nerve also degenerates, and further that the cells from which its axons originate show degenerative changes, explained as being due to "reaction at distance." Hence it is evident that there is a close interdependence between the nerve cell and its processes.

The study of degeneration gives very strong testimony in favor of the neuron idea, since it is found to be quite sharply limited to the cell and its processes. Diseases due to poisons also show a special tendency to be limited to certain neurons. To review the evidence in favor of the neuron theory, embryological studies distinctly show the development of each nerve cell and its processes from an individual, primitive cell, the neuroblast; the microscopical anatomical methods, mentioned above, clearly put in evidence the independence of each neuron. Physiology presents nothing incompatible with the neuron concept, while pathology is entirely in favor of it.

Let us now consider the other side of the question. In order to do this, it is necessary to review briefly the researches which have led up to conclusions apparently in startling contrast to those mentioned above, and which if confirmed will compel a considerable modification of our ideas. As early as 1871, Max Schultze asserted that both the axis cylinder and the ganglion cell possessed a fibrillary structure, and even suggested that the fibrils entered the cell through the protoplasmic processes, to pass directly into the axon. Since his studies were made on quite imperfect preparations, and his conclusions were largely speculative, we are struck with his intuitive genius, now that his ideas seem likely to be confirmed by actual specimens. That cells in other regions are connected by intercellular bridges is admitted. Why not in the nervous system?

Dogiel, after a series of investigations upon the retina—a nervous structure—has affirmed that in it groups of cells of the same kind are connected by a veritable anastomosis of their protoplasmic processes. His conclusions have been supported by some, and disputed by other competent workers using the same method. Recently (1897) Apathy, working with specially developed methods upon the nervous system of the leech and of the earth-worm, has secured beautiful preparations, the study of which has brought over to his views a number of competent observers to whom he has demonstrated them. Apathy is of the opinion that the conducting element in the nervous system is composed of fine fibrils, the primitive fibrils ("leitende Primitiv-Fibrillen") which make up the axon. Each of these fibrils is made up of still finer fibrils—the elementary fibrils—and each forms an anatomically independent entity. Whence come these primitive fibrils? They anastomose and form a network, both within and around the nerve cells and also in the muscles and other structures at the periphery, forming, as it were, an endless chain.

Apathy divides the cells of the nervous system into nerve cells and ganglion cells, the former producing the conducting element, the fibrils; the latter what is to be conducted, the nervous impulse. He distinguishes between sensory and motor fibrils, the former being extremely fine, the latter much thicker, but few or only one being contained in a nerve fibre. The motor fibrils come direct from the ganglion cells. The sensitive nerve fibrils pass into the nerve cells, and dividing into their elementary fibrils form an anastomosing, intracellular network more or less extensive. In other cells the sensitive fibrils form equally a network which occupies the periphery of the cell. From this network fine prolongations are given off, and these converge to a network at the centre of the cell. This central network is composed of coarser fibrils. These latter unite again to form a much thicker fibril, which passes out of the cell and may be traced into a motor fibre.

The cells of the animals examined being unipolar, their single processes are traversed at the same time by both sensory (afferent) and motor (efferent) fibrils. Other sensory fibrils arriving in the ganglion do not proceed directly to the cells, but breaking up form an extracellular network from which fine fibrils are given off. These last fibrils passing into the cells go to make up the intracellular network. The motor fibrils, then, do not arise from the ganglion cells, but are directly continuous with the sensory fibrils through the nervous network. The ganglion cells seem to be simply intercalated like the cells of an electric battery in a circuit. Extending his investigations to the spinal cords of the fish, the newt, and the ox, Apathy has felt justified in claiming that the same arrangement exists in vertebrates. The sensory fibrils passing in through the protoplasmic processes form a network occupying the whole area of the somatoplasm. Leaving this network, the elementary fibrils gradually unite again into the coarser primitive fibrils, which leave the cell by the axon, which they make up. Apathy began his investigations some fourteen or fif-

teen years ago, but his work did not attract much attention until recently. Bethe, who had studied Apathy's preparations at Naples and had become converted to his views, working along similar lines with a special technique developed by himself, has partly confirmed and extended, and partly modified Apathy's deductions, at the same time bringing them widely into notice. Bethe has studied especially the nervous system of a species of crab (Carcinus mænas) and has been able to demonstrate the nerve fibrils with astonishing clearness. According to him the finest ramifications of both axon and protoplasmic processes anastomose one with another to form a network so intricate that it is impossible to say which fibrils belong to one neuron and which to another. Sensory fibrils arriving in a ganglion divide into their elementary fibrils, which become lost in the nervous network. Through this network these fibrils may be continuous with the motor fibrils without passing through a cell. The fibrils observed in the protoplasmic processes and axons are not all in direct connection with the cell body; only a few proceed to the central protoplasm, the others pass in by one prolongation and out by another from neuron to neuron. Hence all the nerve elements are in direct continuity, and if the neuron concept implies entire anatomical independence it must fall to the ground.

The Golgi method he declares is incomplete, since it colors only the external sheath of the conducting element, and not the conducting element itself, hence fails to show the connection from neuron to neuron. Bethe fails to find the intracellular network of Apathy, but regards the motor fibrils as arising from the extracellular network. His statement that the conducting fibrils sometimes pass into a cell by one protoplasmic process and out by another, if correct, proves that conduction in these processes is not always cellulipetal. A close examination of his statements, however, shows that he does not say positively that either in the crab or in other animals he has seen sensory fibrils pass directly into motor fibrils, but he assumes that such is the case.

In studying the nervous system of the crab Bethe found that, in the ganglia from which the antennæ are innervated, the large motor cells are situated around the periphery of the ganglion. Each cell gives off a process which passes to the centre of the ganglion and gives off a number of branches there, then leaves the ganglion with the nerve to the peripheral muscles. The centre of the ganglion is entirely occupied by a network of fibrils, the neuropile formed of these motor fibrils and of sensory fibrils coming from the periphery. Choosing the ganglion connected with the second antenna, he, by a series of cuts, separated the motor cells at the periphery. He found that, after the animal had recovered from the shock of the operation, it could move the antenna in question. Tonus was preserved, and reflexes occurred as usual, except for slight exaggeration. This persisted for several days, and then the antenna slowly became paralyzed. If, on the contrary, the motor nerve to the antenna was cut, paralysis of the latter was immediate and complete. This experiment would seem to show that the tonus and reflexes are independent of the nerve cells and can occur directly through the intermediary of the neuropile. That the influence of the nerve cell is not indispensable, however, is evidenced by the occurrence of paralysis after a certain period.

The views of Apathy and of Bethe have found both supporters and opponents among those equally qualified to form an opinion. It is claimed by Held that the extracellular network of Apathy is non-nervous in character. Bethe's physiological experiment has been objected to on the ground that he failed to remove all of the active part of the ganglion cells, enough being left to furnish the nervous impulse. It is impossible to dispute the presence of the intracellular network, say those who have examined the preparations of Apathy, and his drawings are but a faithful representation of his specimens. The preparations of Bethe are said to show the neuro-fibrils with a clearness which is "stupefying." Now, according to Bethe, these fibrils traverse the body of the cell, but neither branch nor anastomose there. Here, then, is a discrepancy between the two observers. No one else seems so far to have been able to obtain preparations comparable to those of either Apathy or Bethe. Their methods evidently require skill and experience in a high degree. Nissl, in an article which has attracted a good deal of attention, rather contemptuously thrusts aside the neuron theory as utterly discredited. He is evidently no friend of the Golgi method, and says with regard to it: "By it it is impossible to say what is blackened and what is not." He recognizes the existence of the neuro-fibrils, and says that Bethe's method colors the part of the cell left uncolored in his (Nissl's) method. This he regards as the functionally active portion of the cell, consisting in part of the fibrils. The active elements of the nervous system, he thinks, are the nerve cells, and an intercellular gray matter which probably consists in part of the neuro-fibrils, but of whose origin and of whose exact constitution he confesses ignorance. The whole article seems largely hypothetical, and cannot be said to give any new facts. Balancing the evidence for and against, as it exists at the present, what conclusions are we justified in drawing?

To recapitulate: It has long been known that an injury to nerve cell or nerve fibre is followed by degeneration which is sharply limited in extent. The application of the Golgi method shows that each nerve cell (and its processes) is developed from a primitive cell, the neuroblast; hence it forms an embryological unit. Moreover to all appearance the separation of these units, one from another, always remains complete. The neuron conception appears logically to follow. So far, it seems no more proven that the Golgi and vital methylene-blue methods give deceptive results, than that the methods of Apathy and of Bethe do. The latter have had nothing like so wide an application as the former, and more extended investigations seem to be needed before we throw apparently so faithful a servant overboard. There seems a good deal of difference in the conceptions of different authors as to just what the neuron means. It will be remembered that the idea of continuity between neuron and neuron has never been without supporters. Even if the views of Apathy are confirmed, and we have to admit a continuity of the neuro-fibrils, it does not seem to follow, necessarily, that we must abandon our idea of the neuron as a functional unit. Its embryological unity is not affected. It may be necessary to modify our views with regard to it, but our conception of the existence of the neuron, as a means of explaining certain facts, we are as yet hardly called upon to give up. Preserving an entirely impartial attitude we can only await the results of further investigations.

Scanty Amniotic Fluid as a Factor in Procidentia of the Cord and Fœtal Disorders.—Imperiale Pastore reports a case in which a deficient amount of amniotic fluid induced prolapse of the cord, the predisposing cause being a deformed pelvis. Fœtal disorders in such a case when the membranes are intact may be due to pressure exerted upon the funis and compression of the head or, during labor, to the unequal pressure of the tumor upon the prolapsed cord. —*La Riforma Medica*, November 10, 1900.

A FEW REMARKS ON THE USE OF MEDULLARY NARCOSIS IN OBSTETRICAL CASES.

By HUGO EHRENFEST, M.D.,

ST. LOUIS, MO.

Among the numerous reports concerning the use of medullary narcosis we find comparatively few dealing with the employment of this new method in obstetrical practice. But it is almost certain that the encouraging reports of Marx[1] will induce many physicians to try this method.

A careful study of all articles that I have been enabled to collect creates the doubt in my mind, whether we are yet justified in recommending the subarachnoideal injections of cocaine to the obstetrician for general use. The reports, as published in nearly every number of American journals with reference to the use of this method, seem to place special weight on the more or less dangerous symptoms following the use of the injections. The only scientific value of such publications will be to gather material for statistics of morbidity and mortality. Should the percentage of unfavorable cases[2] be found high, medullary anæsthesia will disappear as have other forms of narcosis which, after their discovery, were lauded as ideal. But it occurs to me that the accounts of the use of this method in obstetrics should not be limited to describing the dangerous symptoms in mother and child. To my mind these cases offer a special opportunity for estimating the value of this new method from other points of view.

The two main indications for the employment of subarachnoideal injections of cocaine in obstetrical cases are, first, to produce a painless labor in normal cases, and, secondly, to substitute this method for other forms of narcosis when such is deemed necessary. To produce painless labor seems to have been the predominant idea in the experiments so far made. Doléris and Malarctic[3] concede this as their object. Marx[4] says: "But at last, so far as we are concerned, it is a method ideally suited to mitigate or absolutely allay the dreadful pains of a normal labor."

To accomplish such a purpose, however, according to my opinion, we must make use only of a method—(1) which does not carry with it too great a danger for either mother or child, (2) which does not produce conditions more disagreeable than the pain that we are endeavoring to assuage, and (3) which does not produce complications during parturition, *i.e.*, does not change a birth, which under ordinary circumstances would be normal, into instrumental delivery. In reference to these three points I would like to make the following comments:

1. No one should at present state that medullary narcosis is a harmless procedure. An exact opinion with reference to this point can be arrived at only after the above-mentioned statistics of morbidity and mortality are established. 2. All reports tell of disagreeable symptoms following these injections, viz., vomiting, intense headache, etc., sometimes lasting longer than after the usual chloroform or ether narcosis. Cases of immediate high elevation of temperature with deep collapse are on record:[5] such a great risk, indeed, does a woman take in exchange for labor pain. 3. This point is by far the most important, and necessitates a further discussion. Most of the authors (Kreis, Doléris, Malarctic, Marx) state that the uterine contractions were observed during the anæsthesia. According to their observations there seems to be no change in their frequency, but of course whether their active power is of the same value during the anæsthesia remains to be determined. One thing, however, is positive—the active help of the abdominal muscles is lacking. Naturally, the patient can bear down when asked to, or when she herself is so inclined, as strongly as under normal conditions, but as a consequence of the painlessness the reflex action is not brought on, which causes the automatic help of the abdominal muscles, nor is the woman able to bear down synchronously with the uterine contractions, since she does not feel them. From our knowledge, based on modern views of the great importance of abdominal pressure in the last stage of labor, we should consider its loss to be a very decided disadvantage.

Schroeder was the pioneer in demonstrating by clinical studies the necessity of the help of the abdominal muscles in the expression of the fœtus. At the present time his opinion is generally accepted and is to be found in the principal text-books.

Olshausen and Veit[1] say: "When the delivery approaches its close, and when especially this termination is a difficult one, then the abdominal pressure becomes more important, while the effect of the uterine contractions becomes less." On page 587 we find the following statement: "Complete deficiency of abdominal pressure during the expulsive stage is fortunately very rare. There are only a few records of deliveries in cases of paralysis of the lower part of the body. But in these cases the second stage of parturition seemed to be very much delayed." Probably in those cases the paralyzed perineal muscles offered less resistance to the child's head. This advantage is lacking in medullary narcosis.

Ahlfeld[2] expresses the following opinion: "During the last (second) stage of parturition we can only consider the effect of the abdominal pressure, the influence of the uterine contractions being very inferior to it." "A primary inability to use the abdominal muscles is rare, but even in entirely healthy parturients the inactivity of these muscles sometimes disturbs the normal course of labor to a very marked degree."

Schatz and Poullet endeavored to measure the abdominal pressure by means of a manometer, and demonstrated the fact that during the expulsive stage the pressure produced by the abdominal muscles is nearly as great as that of the uterine contractions.

Galabin[3] says: "The effect of the auxiliary muscles is therefore to add to each of the resultant forces already mentioned. It has also another influence of great practical value, namely, that it tends to press the uterus, as a whole, toward the pelvis. This takes off the tension placed by the uterine contractions on that lower distensible uterine segment, which . . . is the part of the uterus most liable to rupture. Thus the tendency to rupture of the uterus is resisted by an efficient action of the auxiliary muscles, and is more likely to occur if the abdominal walls are weakened."

In Hirst's "System of Obstetrics" (Philadelphia, 1888) Parvin in his work[4] says: "These [abdominal] contractions are chiefly voluntary, only at the close of the second stage of labor do they seem to escape entirely, or almost entirely, the dominion of the will. Such contractions exerted during the first stage of labor, and usually in the second stage, if not synchronous with uterine action, are worse than useless."

[4] "Anomalies of the Forces in Labor," p. 702.

I could recall easily a larger number of opinions of well-known authors, all expressing the same idea on this subject. By studying the histories of the obstetrical cases in which medullary anæsthesia was employed the correctness of these views, to my mind at least, seems to be proven. I have taken into consideration only those cases in which there exist tolerably exact histories, viz., the six cases of Kreis[1] and twenty-three cases of Marx.[2] Out of the six cases of Kreis it was necessary to finish three by means of forceps. The causes assigned were: in one case exhaustion of the mother and insufficiency of the labor; in the second, symptoms of asphyxia of the fœtus; while in the third no cause is mentioned. Among the twenty-three cases of Marx there were twenty-one cases of labor. Of these it was necessary to apply forceps in seven cases. Unfortunately, the indications for this procedure are not mentioned. However, it is worthy of note that the three operative cases of Kreis and these seven of Marx were in primiparæ. The non-elasticity of the perineum—as characteristic of primiparæ—may have made the last stage of confinement more tedious, the abdominal pressure not exerting a helping influence. Of the subsequent nineteen deliveries in which medullary narcosis was employed by Marx,[3] in nine were forceps used. Naturally, as we have no data giving in detail the indications for the use of instruments in each case, we are at a loss to draw correct conclusions. At any rate, the remarkably high percentage of forceps deliveries is very striking, particularly when there was no note of any abnormalities of either the pelvis or the child. At least it is supposed that none existed, as otherwise they would have been reported in the histories.

According to my view it is very necessary in future descriptions of confinements under medullary narcosis, in which obstetrical operations have to be performed, to give exact details of the indication of each operation, to remark all abnormalities in the course of confinement, such as marked delay during the expulsive stage, excessive stretching of the lower segment of the uterus, rupture of the uterus, etc. It is also indispensable to measure the diameters of the pelvis and child's head, to describe the forms of both, and to make note of all abnormalities if they exist.

Should we, however, prove that the parturition is in nowise harmed by medullary anæsthesia, such a discovery would be of the greatest scientific interest, forcing us, as it would, to change our opinion with regard to the value and importance of abdominal pressure.

On the other hand, should we find out that we are compelled to make use of the forceps more often than under the usual conditions, as a consequence of the deficiency of a normal automatic help of the abdominal muscles, this condition alone would contraindicate the use of medullary narcosis as a means of making a normal labor painless. Notwithstanding the best anti- and asepsis, subsequent puerperal or gynæcological diseases are invariably more frequent after delivery by operative procedures.[4]

The second indication for the use of cocaine anæsthesia of the spinal cord, as before mentioned, is as a substitute for other narcosis in cases in which such a procedure becomes necessary either for purposes of examination or operative work. In regard to this indication the remarks I made in discussing points 1 and 2 (danger to the patients and disagreeable symptoms) are to be taken into consideration. I would add to those only the statement of Marx, in which he says: "Explorations, versions, extractions, placental removal, were readily done not with quite as great ease as under chloroform."

In the event that future work along this line establishes the fact that subarachnoideal injections of cocaine are free from danger, they may add some advantages in cases in which heart failure, nephritis, etc., contraindicate the use of chloroform or ether. In country practice it might prove profitable, as one assistant—the anæsthetist—could be spared (Kreis). So, in conclusion, it seems to me more than doubtful whether we are justified at the present time in recommending medullary narcosis as a means of rendering normal labor painless or as a substitute for light chloroform narcosis, which is always sufficient for the usual obstetrical operations.

PERFORATION OF A TYPHOID ULCER WITHOUT FÆCAL EXTRAVASATION; OPERATION FOUR HOURS AFTER THE FIRST SYMPTOM; RECOVERY.

By E. G. CUTLER, M.D.,

physician to the massachusetts general hospital,

and

JOHN W. ELLIOT, M.D.,

surgeon to the massachusetts general hospital.

Without discussing the comparative merits of the terms "pre-perforative stage" (Cushing), "pre-perforative necrotic area" (Cobb), perforation without extravasation, etc.; they all describe the all-important moment for operating on a typhoid ulcer. We early learned in appendicitis that the peritoneum was often infected before the appendix was perforated and we now know that the same thing is true in a typhoid ulcer. The mortality of these operations will depend largely on the extent of the septic peritonitis present at the time of the operation. If we could more often make sure that an ulcer was about to perforate or was slowly infecting the peritoneum our results would be much improved. This single case is offered then as one of a few already observed in which the early symptoms were sufficiently well marked to induce the physician in charge to operate before an opening in the intestine had actually occurred.

C. S——, worker in a woollen mill, nineteen years of age, single, a native of Italy, lives in Lawrence, Mass. He entered the Massachusetts General Hospital, March 9, 1899, for treatment of acute enteritis, and was discharged March 14th, much relieved. The family history was good; he occasionally used alcohol, but his habits were otherwise good; his personal history was negative, he denied having had venereal disease. He entered the hospital again, May 31, 1899.

Present illness: Since leaving the hospital he had been well until about one week ago when he became feverish (no chill), had headache and loss of appetite. He vomited three times the day before admission, but not before or since. He had no cough at first, but has a slight cough now; there is no pain anywhere, he has had no nose bleed, and the bowels are constipated. The patient had not been in bed until the day before admission.

The patient was well developed and nourished, swarthy; his face was slightly flushed, the skin was hot and dry, the pupils and reflexes were normal; there were no enlarged glands; the teeth were fair but dirty; the tongue was dry and coated; the pulse was regular, of fair volume, dicrotic, and moderately compressible; the lungs were normal; the heart area was not increased; the apex beat was felt in the fifth interspace three-quarters of an inch inside the nipple

line; the second sound was sharp; the pulmonary second sound was not increased; the first sound was reduplicated. The liver was not enlarged; the spleen was enlarged to the costal margin. There were one or two rose spots on the chest; the abdomen was slightly distended and tympanitic but not tender. The blood count showed white corpuscles 7,600; Widal's reaction was absent; the urine was high colored, acid, 1,028 specific gravity; there was a slight sediment; of albumin there was the slightest possible trace; sugar was absent; chlorides were normal; diazo reaction was absent; an occasional small round cell and an abnormal blood globule were found; there were fairly many leucocytes; an occasional squamous cell, and large round cells like those of the neck of the bladder; no casts were seen. The patient was put upon liquid enteric diet; baths were given according to schedule; special precautions were taken.

On June 6th the man was reported about 5 A.M. for pain in abdomen. He had a pinched expression. The abdomen was rigid, more in the right lower quadrant, slightly tympanitic; there was general tenderness, more marked in the right lower quadrant. A high soap-suds enema was given with turpentine one teaspoonful, and a turpentine stupe was applied. The patient had a large dejection about 6 A.M. He was reported again at 6:45 for severe pain and vomiting; vomitus was of food only. Liquid Dover's powder, ♏ x., was given. At 7:45 the patient was still in considerable pain. He lay on the left side with knees flexed. The countenance was anxious and there was an evident expression of severe suffering. The face was somewhat whiter than usual but not markedly pale. The pulse had risen from 90 to 120 per minute, with but little or no alteration in volume. There was no fall in temperature. The abdomen was generally rigid but more so in the right lower quadrant; the tenderness was general but most marked over this area; the abdomen was slightly tympanitic as before. The white corpuscles numbered 17,200. The Widal reaction was present in twenty-five minutes. The patient was seen about 9 A.M. by Dr. Elliot, who concurred in the diagnosis of perforation of the intestine, and the patient was transferred at once to the surgical side. E. G. C.

Dr. Elliot found that the patient, in the third week of typhoid fever, had been attacked with a sudden severe abdominal pain four hours earlier. He was still suffering greatly in spite of a small opiate. The abdomen was moderately distended, rigid, and tympanitic. There was no dulness and nothing abnormal could be detected by palpation except a general tenderness. The white blood count had risen from 8,000 the day before to 17,000. Pulse, 110; temperature, 103.8°. The patient had the expression of a very sick man. It seemed quite evident that an acute peritonitis was beginning and the perforation of a typhoid ulcer was considered to be the most likely cause, although an acute inflammation of the gall bladder was considered a possible cause. A laparotomy was done at once. When the abdomen was opened in the median line the peritoneal cavity was found filled with a turbid fluid containing white fibrinous flakes. The intestines were darkly reddened and congested. Several adherent patches of greenish-white fibrinous exudation were seen on the intestines. The intestines were not glued together. The picture was that of a general septic peritonitis which was most acute in the neighborhood of a certain part of the small intestine. The cæcum presented and the appendix was found to be normal. The ascending colon was withdrawn and examined; the ileum was next traced upward from the cæcum. The ileum was more reddened than the colon and about four feet from the cæcum a gray fibrinous mass covered the surface of the gut. This coil of intestine was withdrawn from the wound and surrounded with gauze. On the side opposite the mesentery an ulceration was plainly to be seen, the centre of which was just ready to slough out. It was difficult to know how much leakage had taken place and gentle pressure failed to force the fæces through. The ulcer appeared as an indurated area about as large as a quarter of a dollar, which was deep red in color and in the centre of which was a gray crater the size of a pea, which had lost its peritoneal covering and looked very friable and disorganized. The mucous membrane of the bowel was not seen and it was not considered wise to probe the opening, but it was quite evident that some of the infectious contents of the intestine had passed through to give rise to the general peritonitis. Other small patches of fibrin were seen on the bowel in the region, but no other ulceration was found.

Lembert silk sutures were so placed as to fold the gut longitudinally over the perforation, a second layer of sutures being placed to cover in the first series. The abdomen was very carefully wiped out with gauze sponges; the patient being first raised to a sitting posture to cause the turbid fluid to flow into the pelvis. The patient was then placed in the Trendelenburg position and the pelvis wiped out with great care. There was no irrigation of the abdomen. The wound was closed, leaving a small thread of gauze drainage at the lower angle leading down to the line of sutures.

The patient was not in a critical condition after the operation, but bore it fairly well, considering the general typhoidal condition. Pulse, 120; temperature, 104.5° that night. On the following morning the temperature was normal and pulse 90. On the third day the bowels were moved by an enema, and on the fourth day the gauze drainage was removed. The wound healed by first intention. The patient was generally comfortable without opiates and complained only of hunger. He was given liquid diet with large nutritive enemata, but on the sixth day he was allowed soft-boiled eggs and a larger quantity of liquids. On the eighth day his temperature rose to 104.8°. As there seemed to be a relapse in his typhoid, he was then transferred back to the medical wards where he again came under Dr. Cutler's care.

J. W. E.

June 15th: Relapse began on the 13th.

Examination shows the abdomen considerably distended, rigid, and tympanitic, not tender. The spleen, increased to costal margin, was not palpable. The wound was healed, and covered with collodion dressing. The pulse was regular, of fair volume, rather easily compressible, and dicrotic. The tongue was dry and coated. White corpuscles 7,000. A few rose spots on abdomen. For the next twelve days the patient was fairly ill with his relapse, when there was lysis and an uneventful convalescence followed.

The patient now, on January 8, 1900, reports himself as perfectly well in every way. E. G. C.

Bacteriological Examination of the Blood in Pneumonia.—A. Prochaska attributes the conflicting results reported by different investigators who have studied this subject to the fact that insufficient quantities of blood have been taken for the purpose. In using small amounts he himself obtained very irregular figures, but on taking the material directly from a vein and adding 4–5 c.c. to bouillon positive results were noted in every one of ten cases examined. These were chosen indiscriminately, without regard to the severity of infection, and four presented complications such as empyema, acute nephritis, and gangrene of the lung. In every instance pure cultures were obtained at the first sowing.—*Centralblatt für innere Medicin*, November 17, 1900.

ON THE TREATMENT OF LARYNGEAL TUBERCULOSIS.[1]

By ROBERT D. COHN, M.D.,

SAN FRANCISCO,

OCULIST TO THE MOUNT ZION HOSPITAL; SURGEON TO THE CALIFORNIA EYE AND EAR HOSPITAL.

If I take the liberty of encroaching upon your patience with a few remarks on the treatment of laryngeal tuberculosis, it is because the theme is one that interests not only the throat specialist, but the general practitioner as well. Before we proceed to our subject proper, a few words may not be out of place on the pathological anatomy of the affection under consideration, for the reason that an understanding of the morbid processes involved in laryngeal pthisis is essential to any rational treatment.

Tuberculous laryngitis begins with an infiltration in the lower layers of the mucosa and in the submucosa. The question as to how the tubercle bacilli reach the lower layers of the mucosa and the submucosa is here immaterial. Whether those investigators are right who contend that the infection takes place from the surface, the germs entering in through the epithelium, this having suffered previous structural changes, or whether the others are correct who maintain that the germs find their way into the lower layers from the lung and bronchial lymphatics by way of the blood and lymph channels—that question is for our present purposes irrelevant, as it has no bearing upon the treatment of the affection. For the treatment only one circumstance is of importance—the circumstance that the first morbid changes begin, contrary to a still very general belief, not on the surface but in the deeper strata of the larynx. In other words, tuberculous laryngitis does not begin as a superficial ulceration that secondarily creeps inward, but as a deep-seated infiltration that spreads outward until it reaches the surface, when it ulcerates. With the sole exception of aphthous ulcers, which result from the action of irritant sputa coming in direct contact with the surface of the larynx in pulmonary phthisis of long standing, the mucosa, above all the epithelium, is in the initial stage of laryngeal tuberculosis intact, the surface smooth. Deeper down in the lower layers of the mucosa and in the submucosa the primary infiltration appears. If in this stage lactic acid or any other cauterizing agent be applied, how is it to influence the morbid tissue? It produces merely an erosion or an ulceration which heals of itself, without having had the slightest effect upon the tuberculous process. Let us take for instance the changes upon the posterior laryngeal wall. Here, as everywhere else in the larynx, the primary process is a deep-seated infiltration, which later extends on the one hand still farther inward till it reaches the perichondrium, causing there ankylosis of the crico-arytenoid joint, or on the other hand spreads outward toward the surface, on reaching which it sends forth granulations which extend into the lumen of the larynx. Secondarily these granulations ulcerate, exactly as in the case of neoplasmata, and we then have for the first time an ulcer, so that the sequence is infiltration, granulation, ulceration. Often in the primary stage the patient cannot phonate, because the swelling of the posterior wall prevents in a purely mechanical way the vocal cords from approaching each other. In the third stage, a year or two later, he can once more phonate, for the simple reason that the swelling and the granulations on the posterior wall have disappeared and given way to an ulcerated surface, thus permitting an approximation of the cords. He naturally believes his condition changed for the better, whereas, in fact, it has changed for the worse. The return of the voice denotes in this instance progression not retrogression of the tuberculous process. I dwell on this point because only a few years ago the opinion prevailed very generally that in tuberculous laryngitis hoarseness and development of the disease keep equal pace—the greater the degree of hoarseness the farther advanced the disease—whereas, in point of fact, the reverse is often the case. These briefly sketched changes on the posterior wall are in all essential respects the same that occur in the various other parts of the larynx.

We now come to our subject proper. Before the invention of the laryngoscope the treatment of laryngeal phthisis was necessarily limited to general therapeutics, dietetics, and hygiene. It is true numerous attempts were made to treat the affected parts locally, but without success. On the one hand all manner of inhalations, sprays, etc., were used, which at best gave a certain temporary relief; on the other hand the various astringents and cauterizing agents were introduced blindly into the larynx by means of bent probes, and probably did more harm than good. It is therefore easy to understand the extravagant hopes raised by the invention by Czermak and Tuerck, of Vienna, in 1858, of the laryngoscope. As if by magic the entire larynx was now exposed to view and nothing seemed more easy or more certain of success than carefully localized treatment. The ulcers were diligently cauterized with silver nitrate and copper sulphate, and a bitter disappointment followed. The outcome of every effort was the disheartening confession that cauterization was of no avail, the tuberculous process went its way in spite of it, and medical skill was as helpless as before. Hence a few years later Stoerk, professor of laryngology in Vienna, formulated the principle that tuberculous laryngitis is a noli me tangere—it is forbidden ground, no local treatment is permissible. The principle found general acceptance, and until the end of the seventies tuberculosis of the larynx was considered an incurable disease.

In 1880 M. Schmidt, who with others had pronounced this pessimistic standpoint inhuman, announced that he had discovered a simple method of healing a tuberculous throat ulcer by means of inhalations of three-per-cent. carbolic acid. The method was eagerly seized upon and tried with results which, while they by no means justified Schmidt's enthusiasm, showed that he had hit upon a procedure of great value. The reason for his mistake in supposing that he had found a cure was the following: the tuberculous ulcer is only in the beginning specifically tuberculous, a secondary strepto- and staphylococci invasion very soon takes place, and we then have a mixed ulcer; so that every tuberculous throat ulcer, except those entirely fresh, is mixed. Schmidt's carbolic inhalations had had the effect of removing the secondary products, the dirty grayish coating. The original tuberculous ulcer with rosy, healthy-looking granulations remained. This Schmidt mistook for the healing of the ulcer. In other words, with carbolic acid or any other antiseptic agent we cannot influence the tuberculous process as such, but we can prevent secondary infection. Is it now of any benefit to the patient if we do this? It most certainly is. For it is secondary infection that produces swelling of the larynx, with dyspnœa and dysphagia, and the dysphagia of laryngeal tuberculosis is one of the most terrible things that are. It is secondary infection, moreover, that is responsible for acute perichondritis of the crico-arytenoid joint. Without warning, over night, chill and fever set in, the entire capsule of the joint becomes infiltrated, and the arytenoid cartilage swims in pus, all in twenty-four hours. Tuberculous granulations that had existed for months on the posterior end of one of the vocal cords had finally ulcerated, where-

[1] Read before the San Francisco County Medical Society, October 9, 1900.

upon strepto- and staphylococci from the surface had entered and produced a violent inflammation of the joint. A tuberculous process existing for months alone never bursts out as suddenly as that—that is always the work of secondary infection. By preventing this we prevent all such occurrences, and if we thereby spare the patient during the last week of his life that awful dyspnœa and dysphagia we have done at least our duty. Whether we use carbolic acid, creosote, glycerin, menthol, or iodoform, is immaterial.

Schmidt's carbolic inhalations having failed to realize expectations, the search for remedies was continued. In 1885 the Vienna surgeon Mosetig recommended lactic acid in tuberculous affections of the knee. Impelled by Mosetig's success attendant upon the use of the acid, Krause, struck by a fortunate inspiration, in that same year made a trial of the remedy in the throat. He began to cauterize the tuberculous ulcers with lactic acid, and with success exceeding anticipations. His reports were so glowing that a large number of laryngologists immediately availed themselves of the method with results equally good, and from that day to this lactic acid has remained by far the most efficacious remedy in laryngeal phthisis. As Schech says: "It acts almost specifically in that, while it attacks the morbid tissue, it leaves the healthy tissue intact." If any agent can bring about the cicatrization of a tuberculous throat ulcer, it is this acid. Its employment is limited, however, to open processes, that is, to ulcerated surfaces, and does not extend to non-ulcerated infiltrations, for if the surface be intact it cannot penetrate to the morbid tissue underneath. Moreover, the method of application must be rational. The treatment of tuberculous ulcers with twenty- to thirty-per-cent. lactic acid, as often practised, is unavailing, as that concentration is too weak to accomplish the purpose intended. One must use a fifty- to eighty-per-cent. solution, which must be rubbed so energetically into the ulcer that a brownish or blackish eschar results. For this reason I agree with Lennox Browne in thinking the advocacy of application by means of the laryngeal spray ill advised. Some apply the acid daily or every second day; this is an entirely irrational procedure. The application should not be repeated until the eschar sloughs through reactive irritation—a process requiring from seven to fourteen days. In the mean time insufflations of iodol, iodoform, or another disinfecting powder are in place. Preceding every cauterization a thorough cocainization is necessary, a fifteen- to twenty-per-cent. solution being the strength generally required. On the detachment of the eschar the surface is smooth, the superficial granulations having been actually destroyed by cauterization. The chief deposits, however, are still below, and the cauterizing procedure must therefore be repeated four or five or a dozen times, often through many months, before we can hope to have entirely eliminated the morbid tissue.

And yet it is not permissible in every case in which there are tuberculous ulcers in the larynx without further consideration to apply lactic acid. In this Bosworth goes too far, in my estimation, in stating that "in view of the excellent results which have followed the lactic-acid treatment, we have not done our full duty in any given case without fully testing its efficacy." Several strict indications must first be fulfilled. In the first place, the ulcers must be circumscript. If, for instance, the posterior wall, both vocal cords, and one or both arytenoid cartilages be already ulcerated, lactic acid is strictly forbidden, for such ulcers do not heal, even with lactic acid. One ulcerated vocal cord or an ulcerated posterior wall has a fair chance of healing; these plus additional ulcers have practically none whatever. In the second place, the general condition must be good. If the pulmonary process be already far advanced or advancing rapidly, if the appetite be poor, or if the patient do not tolerate cocaine, cauterization should not be undertaken. If the patient's appetite be ruined with cocaine, the greatest harm is done him, for as long as the tuberculous subject's appetite remains good, there is always hope of eradicating the disease or at least of checking its progress. So much for tuberculous ulcerations. I repeat that lactic acid is the sovereign remedy in their treatment; that, as Solis Cohen says, there is nothing else which bears comparison with it, that it acts almost specifically, and that, if the above-mentioned indications be fulfilled, its use is imperative.

We now come to the tuberculous infiltrations. After the introduction of lactic acid in the treatment of tuberculous ulcers, Heryng hit upon the idea of treating tuberculous infiltrations by the same means, cauterization being preceded by multiple scarifications. The object of these was to convert the non-ulcerated infiltration into an open process, into which the acid could then be rubbed. Although diminution in size of the infiltration and cicatrization of the wound frequently followed, Heryng soon saw the inadequacy of the procedure and devised in 1887 the method upon which the entire present surgical treatment of laryngeal phthisis is based, and that is curettage. The single curette is an oval sharp spoon, the curve of which is adapted to the various regions of the larynx. With it the tuberculous infiltrations are thoroughly scraped with the intention of eliminating the tuberculous products and leaving a wound which later cicatrizes. There are, however, certain parts of the larynx to which, on account of their lack of tenseness, we cannot apply the single curette; these are the epiglottis, the ary-epiglottic folds, and the posterior wall. For these parts we use the double curette. It acts, moreover, more energetically than the single curette, and is therefore adapted to those infiltrations, irrespective of their localization, which by reason of their hardness do not yield to the single curette. It is needless to add that before the employment of the curette the larynx must be thoroughly cocainized, for which purpose, as in the application of lactic acid, a fifteen- to twenty-per-cent. solution is necessary. On account of the sensitiveness and excessive reflex irritability of the posterior wall, this region is the most difficult to manage. With the single curette hemorrhage is slight, with the double curette more profuse. This danger is, however, not very great. In case of trouble a mixture of lactic acid and liquor ferri sesquichloridi in equal parts will be found serviceable. After the operation insufflations of idoform, iodol, aristol, or a similar disinfecting powder are all that is necessary. The reaction is slight; at worst the patient complains of rawness in the throat and painful deglutition, sometimes of headache and slight fever. As some one has said, many stand the operation better than the cocaine. In general seven to fourteen days must elapse before the operative procedure is repeated. As to the indications for curettage, they are the same as for cauterization with lactic acid, only that in the case of curettage they are, if anything, still stricter.

If now in conclusion I am permitted a brief recapitulation, I should like to divide laryngeal tuberculosis as regards its therapeutics into three stages. In the first stage, with the exception of a circumscript infiltration or ulceration, the larynx is healthy. In this stage (the only one in which we can hope for a permanent cure) the treatment consists in curettage in case an infiltration be present, in cauterization with lactic acid in case an ulcer be present. If the general condition, especially that of the lungs, be good, these procedures are imperative. As above stated,

they must be repeated at intervals of one to three weeks, until the diseased tissue is completely removed.

In the second stage the larynx presents extensive infiltrations or ulcerations. Here we can no longer hope for a complete elimination of the morbid tissue; in other words, if we get the case in this stage we can no longer count on a cure. Here the antiseptic treatment comes to the front, for here our main aim is to prevent secondary infection. The mildest method is by means of antiseptic inhalations; whether we use one- to three-per-cent. carbolic acid, two- to four-per-cent. boracic acid, or one- to two-per-cent. lysol is of no consequence. If the epiglottis permit an inspection of the interior of the larynx the antiseptic swab is still more efficacious, for which purpose a ten-per-cent. solution of carbolic acid in glycerin can be recommended. More in favor than this is a ten- to thirty-per-cent. solution of menthol in olive oil, which acts both antiseptically and analgetically. As above outlined, by means of this antiseptic treatment we forestall secondary infection and thereby the terrible dyspnœa and dysphagia of the last stage.

And, finally, if we see the case first in this last pitiful stage, all that it is in our power to do is to treat it symptomatically, to administer a morphine powder before each meal, or better still to apply a ten- to twenty-per-cent. solution of cocaine to the pharynx. In impending suffocation tracheotomy must, of course, be performed.

I have confined myself entirely to the local therapy of laryngeal tuberculosis. There remains the general treatment — internal medication, dietetics, and hygiene—on which, however, I refrain from dwelling, as it corresponds closely to that in pulmonary tuberculosis.

LOCAL ANÆSTHESIA IN THE RADICAL OPERATION FOR INGUINAL HERNIA.

By LEO B. MEYER, A.M., M.D.,

NEW YORK.

It was my good fortune, not long ago, to assist at an operation for the radical cure of inguinal hernia under local anæsthesia. Personally, I have always operated on hernias with the aid of general anæsthesia. The operation was performed on the house surgeon of a large New York hospital. A careful perusal of the following description, which for simplicity's sake is given in the words of the patient, will, I think, be as instructive to the reader as it was to me, especially so, because the patient underwent the operation by this method for the purpose of testing its merits. The accuracy of the account I can vouch for. The anæsthetic used was eucaine β six per cent. The patient conversed with the operator and his assistants during the entire operation, so as more accurately to describe his sensations subsequently.

"Local anæsthetization: The operation down to the exposure of the external oblique aponeurosis was painless, as was also, practically, the splitting of the latter to expose the cord. The separation of the sac from the cord was excruciatingly painful. The sensation was as if the testicle were being constantly and thoroughly mauled. It was present when the cord was touched ever so lightly; its severity during the stripping of an adherent sac from the cord can therefore be easily imagined. The ligation and excision of a large portion of the omentum was, contrary to every one's expectation, absolutely painless. Traction on the omentum, however, while not actually painful, was responsible for a very disagreeable nausea, which, by the way, persisted for two days following the operation. The introduction of the purse-string suture into the neck of the sac, and the ligation and excision of the latter, were painless. The suturing of Poupart's ligament to the conjoined tendon and its muscles, to construct a new posterior wall for the canal, was practically without pain. On the other hand, the suturing of the external oblique aponeurosis was surprisingly painful, the passage of the needle feeling like a knife passing through inflamed tissues; the drawing together of the edges of the aponeurosis, however, did not cause much pain. The edges of the skin were drawn together with India-rubber zinc plaster, and not sutured.

"While the suturing in itself was on the whole not very painful, it must not be forgotten that during the first part of the procedure the cord had to be held out of the way with a blunt hook, causing the testicular pain previously described.

"The operation lasted sixty minutes. During the first minute there was no pain; during the other fifty-nine minutes the pain was such that should any one who reads this contemplate undergoing an operation for the radical cure of inguinal hernia under local anæsthesia, I should advise him not to. If he wants to know how it would feel, let him give his testicles a good hard squeeze, and imagine the pain lasting from thirty to fifty minutes; then, if he cares to try it, well and good; at any rate he knows what to expect. I, for one, would prefer general anæsthesia, if I had to undergo a similar operation on the other side."

How much less pain the patient would have experienced had the ileo-inguinal nerve been cocainized at the beginning of the operation, according to the method described by Cushing in the *Annals of Surgery*, January, 1900, I do not know. In the only case I have seen this method used it seemed to be ineffectual. The case was one of double inguinal hernia, in a patient who could endure pain well, and who said he was willing to stand a good deal for the sake of a cure. Both sides were operated upon under local anæsthesia, the first side according to Cushing's method, the other in the usual way. The amount of pain experienced seemed to be the same on both sides. Even in the hands of its originator this method is by no means ideal, as may be inferred from statements in the original article, to the effect that morphine and chloroform in small whiffs are excellent adjuvants and have to be used at times, that some pain must necessarily be inflicted, and to spare the patient it is a temptation to slight certain steps. And why, indeed, should any one expose himself to such needless suffering? Every patient whom I have seen operated on in this way has solemnly stated afterward that no power on earth could make him undergo the experience again.

What are the advantages claimed for this method of operating in hernia? In the order of importance they are: (1) absence of the dangers of general anæsthesia, both immediate and remote; (2) absence (usually) of the unpleasant sequelæ of anæsthesia; (3) the aid the patient can give the operator, *e.g.*, by coughing, so that the sac can be more easily isolated. Before considering the advantages further, let me mention the disadvantages: (1) the severe suffering mental and physical which is caused, resulting in more or less shock; (2) the tendency on the part of the operator to hurry and slight certain steps; (3) the condition of neurasthenia in which the operation may leave the patient. The case of double hernia mentioned above is a good example of the last-named disadvantage. For the three months following the operation, during which time I had the patient under observation, he was in a condition of marked neurasthenia, such as is often seen in people who have been in railroad accidents.

Inasmuch as one or more of these disadvantages is always present to a greater or less degree, this method of operating should not be employed unless the ad-

vantages are sufficiently strong to offset them. Of those mentioned (2) and (3) are certainly insignificant —(2) because post-anæsthesia unpleasantness is but temporary, and not always present, and (3) because we can, and in practically all cases do, get along very well without any help on the part of the patient.

I do not wish to be understood as an unqualified opponent of operating upon hernias under local anæsthesia. I simply wish to help in defining its limitations, and since the only real advantage of the method is the removal of the element of danger of general anæsthesia (and this element nowadays is practically nil, except in old people and those subject to certain diseases, such as advanced emphysema, and advanced chronic endocarditis) it seems to me that the method should be employed only in those cases in which the administration of a general anæsthetic is dangerous.

For this reason I believe that this method of operating in hernia should not even be suggested to patients whose condition is good, and in whom the administration of a general anæsthetic is reasonably free from danger. Indeed, it is quite possible that the method will not be practised so extensively, even by those who are now its strongest advocates, if cocainization of the spinal cord prove finally to be as free from danger as recent experiments seem to indicate.

60 West One Hundred and Twenty-ninth Street.

Clinical Department.

REPORT OF A CASE OF FRACTURED LIVER.

By SEELYE W. LITTLE, M.D.,

ROCHESTER, N. Y.

Recovery from this accident seems to be rare, which is the only reason for making this report.

R——, aged thirty-five years, a canaller, was struck in the epigastrium a hard blow with a stick of wood. He was brought to the City Hospital on September 8th for treatment within three or four hours of the accident. On entering he was in collapse; his pulse was small and feeble, his face was pale and anxious, and his extremities were cool. He complained of severe pain in the epigastrium. On examination no mark of injury could be seen. There was no unusual dulness on percussion over the abdomen. Clear urine was obtained by the catheter. There was some vomiting. The diagnosis lay between the ordinary "knock-out" blow over the solar plexus and rupture of some organ with hemorrhage. When the abdomen was opened it was found to contain a large amount of free fluid and clotted blood, and the bleeding was evidently still going on. The first organ examined, the liver, was found to have been torn to the extent of three or four inches on the anterior inferior surface of the right lobe between the gall bladder and the longitudinal fissure. The rent was large enough to contain the ends of four fingers, and was about three-fourths of an inch deep, with ragged sides and edges. The wound was packed with gauze in a gauze bag, which was held in position by a heavy silk ligature passed through the abdomen from the right side behind close to the free border of the ribs to the left side in front just below the rib cartilage at that point. This ligature thus hugged the right lobe of the liver, and, by passing over the gauze packing, held it firmly in place. The ligature was tied tightly on the outside of the body, care being taken to feel that no coil of intestine was caught by the tightened silk. The lower part of the wound was closed, the upper part being left open for the removal of the gauze. For the first day or two there was considerable oozing of blood. Then for about ten days or two weeks there was a profuse discharge of bile, gradually lessening until there was none. The gauze and ligature were removed on the eighth day. The large cavity left by the gauze filled up rapidly, and on October 30th the patient was discharged well.

FRACTURE OF THE CLAVICLE, RESULTING IN RUPTURE OF THE SUPRASCAPULAR ARTERY(?).

By H. T. MILLER, M.D.,

SURGEON, MITCHELL-THOMAS HOSPITAL, SPRINGFIELD, OHIO.

Mrs. B——, aged forty-five years, housewife, was admitted to the hospital last June, giving the history of having fallen in an epileptic attack four weeks previous to the date of admission; upon regaining consciousness she had discovered a swelling, about the size of an orange, over the middle portion of the clavicle on the right side. This swelling had grown very rapidly, and given her considerable pain. An examination revealed a large pulsating tumor extending from above downward from the omohyoid muscle to the fifth rib, and laterally from the suprasternal fossa to the axilla.

At this time a fracture of the clavicle was not suspected, nor had it been by the physicians who had previously attended her: however, a rupture of an artery of magnitude was diagnosed, and it was thought that in all probability an operation would terminate fatally.

Two days after admission to the hospital two incisions were made, one extending from the lower margin of the thyroid gland to the suprasternal fossa, the second incision extending from the latter point to about three inches over the clavicle. The skin, superficial fascia, platysma myoides, superficial layer of the deep fascia, the clavicular and sternal heads of the sternomastoid, and the sternohyoid and sternothyroid muscles were divided. The inferior thyroid veins were divided between ligatures. There was great difficulty in the dissection on account of the close proximity of the tumor, and then there was constant fear of rupturing it. After the subclavian artery had been exposed, it was found that the finger could be inserted between the artery and vein into the substance of the tumor, which was found to be largely composed of disorganized blood clots. A portion of the clavicle was removed, and was found to have been fractured and partly necrosed, probably from pressure. The patient being in severe shock, it was deemed advisable to discontinue the operation and defer further procedure to a future time. However, before the wound was closed, an incision into the tumor was made over the fifth rib, and a drainage tube was inserted from the first incision to the latter opening. The treatment from now on was rather expectant—every day the wound was thoroughly irrigated with an antiseptic solution, and all loose blood clots were removed.

It was soon seen that nothing would be accomplished by this treatment, for as fast as the clots were removed from below more would push down from above, showing that the hemorrhage still continued.

The patient being in a condition to hazard another operation, she was again prepared, and two weeks after the first operation the second was performed.

An incision was made nearly in line with the original, but the hemorrhage here was so severe that this region was at once abandoned, and the incision over the fifth rib, made at the first operation, was enlarged, and the tumor emptied of all clots—we being prepared, however, to cut down at once to the suprascapular artery, which was now thought to be the artery ruptured, should hemorrhage follow the emptying of the

tumor. No hemorrhage following, an incision about five inches long was made over the clavicle, connecting with the original incision. At least two inches of the sternal end of the clavicle had been absorbed, leaving a spiculum of bone as sharp as a needle, protruding into the wound. It was concluded that it was this pointed piece of the clavicle that caused the rupture of the artery, or at least was a contributing cause of the hemorrhage.

Three inches of the clavicle was resected, and a portion of the subclavius and pectoralis major muscles was cut away, owing to a disorganized condition of the muscular tissue, no doubt from pressure. The ruptured blood-vessel not being found, and no hemorrhage following the operation, the wound was closed; not, however, before it had been well packed with iodoform gauze, which two days later was removed, no bleeding following its removal. From now on up to the time I left for my vacation—a week later—the patient seemingly did well; she suffered no pain, was quite cheerful, and gave every promise of making an uneventful recovery.

On my return from my vacation, August 28th, I found the patient very weak and greatly emaciated. The tumor had assumed its original size, but had changed completely in character; it was nodular, the apices of the nodules being blue, and in some places were not connected with the body of the tumor, and honeycombed with sinuses which connected with large cavities containing a foul-smelling, semi-purulent matter. This condition grew steadily worse up to the moment of death, which occurred a few days later.

AN UNUSUAL CASE OF NOSE-BLEED.

By G. W. SQUIRES, M.D.,
EAST AVON, LIVINGSTON COUNTY, NEW YORK.

J. B——, aged fifty years, up to the time of attack considered his health perfect, and worked at his trade of iron moulder. He awoke at night and found blood trickling down the outside of his neck. He called his wife who put cold water on the back of his neck, and gave him a hot mustard foot bath. Home treatment failing to stop the bleeding a physician was sent for, who tamponed the anterior nares and gave ergot. The blood soon appeared at the posterior nares and they also were plugged. Especially in the right naris, which seemed to bleed the more profusely, the packing caused such a feeling of fulness in the nose, eyes, and frontal sinus, that the patient begged to have it removed. This was done under protest, and the escape of a large quantity of blood followed. The patient fainted and showed such effects of hemorrhage that the attending physician, Dr. Goodrick, called me in consultation. I was surprised at the bloody appearance of the bed and the patient's clothes, and remarked that he had evidently lost some blood. The doctor told me what he had done, and what medicines he had given, which seemed the most judicious treatment. The nose was again packed fore and aft with less discomfort to the patient, and to all appearance stopped the escape of blood. The patient was now after forty-eight hours so exsanguinated as to be unable to raise his head; he was partially blind, and nauseated with intolerable thirst. Supporting treatment was used, with hypodermic medication of ergot, digitalis, strychnine, etc., without benefit in checking the bleeding unassisted by tampon. When it was necessary to remove the packing for cleansing purposes, the blood would start to run, and the patient would lose all he had gained for several days. Three physicians were now in attendance in relays, as it seemed the man would die by a short hemorrhage in the absence of frequent stimulations of brandy, strychnine, etc. This state of things went on for ten days, when conditions looked more encouraging: there was less bleeding on removal of the tampon, and the patient was stronger. For two months there occurred occasional but slight epistaxis, when it stopped entirely, and the patient gradually got around again.

About four months afterward the patient, on scratching his nose, felt something sharp in contact with his finger. He called his wife, and asked her to see what was there. She saw the point of something sticking through the skin on the outside of the right nostril, and taking a pair of tweezers extracted a rusty needle an inch long, broken off near the eye. This was, of course, an explanation of the cause of his severe epistaxis. I saw the needle and the place through which it had worked out of the nose. After two years the man has never had another attack of nose-bleed.

The interesting features in this case are the unascertainable cause of the trouble at its occurrence, the sudden alarming and hard-to-control epistaxis in a man of previous good health, the whence and the why of this needle's presence in the nasal cavity of a man of his age and intelligence.

DISLOCATION OF THE CRYSTALLINE LENS IN IMMATURE CATARACT.

By NORBURNE B. JENKINS, M.D.,
CHICAGO.

Dislocation of the crystalline lens usually takes place in advanced life. The thin membrane enveloping the lens ruptures, and the lens passes forward into the aqueous humor or backward into the vitreous humor. Spontaneous dislocation is supposed to be caused by disease or atrophy of the lens capsule. It is probable that immature cataract is often the cause of such dislocation.

In beginning cataract the crystalline lens swells and often increases in convexity so much that glasses are not needed in reading. It has long been known that the lens increases in size in cataract. It is probable that the enlarged lens occasionally bursts its capsule. Intralenticular pressure may cause capsular atrophy, and rupture may follow.

Cataract usually comes in advanced life and in both eyes. The writer's observation goes to show that, in spontaneous dislocation, cataract of the fellow-eye, if not already present, may usually be expected, so constituting a diagnostic criterion.

AN EPIDEMIC OF TYPHOID FEVER.

By BENJAMIN K. HAYS, M.D.,
OXFORD, N. C.

In an unpublished paper on typhoid fever, written by the late Dr. John W. Booth, of Stem, N. C., is the following interesting report of an epidemic which occurred in his practice in 1886: "North of Moore's church is a log house, and near the back of the house is a depression terminating in a gully. In the gully, one-half mile below this house, is a spring which in part supplies water to the congregation at Moore's. A well, some distance beyond the spring, is also used by the congregation. A rock dam turns the water from the spring when flushed by rain, but this dam is not impervious to water. During and just preceding a protracted meeting at Moore's, a negro living in the log house had typhoid fever. Her dejections were thrown into the gully at the back of the house, and were in part at least in a very dilute solution. Of course they were taken by the first rain down the

gully, and, trickling through the rocks, contaminated the water in the spring. The woman first called in medical aid August 3d, and on August 16th a member of the congregation was taken ill of the fever, and was followed by others in quick succession, numbering over seventy in all. Several members of the congregation, including the preacher, had the fever at their homes out of the neighborhood, and were the only cases in their respective communities."

THE REMOVAL OF THIRTY-FIVE SCREW-WORMS FROM THE NOSE.

By HAL FOSTER, A.B., M.D.,
KANSAS CITY, MO.

The patient, Thomas K——, aged seventy-two years, lived in Wyandotte County, Kans. He was admitted to St. Margaret's Hospital September 12, 1900. The nose, eyes, and face were badly swollen. He had excruciating frontal headache, and the discharge from the nose was bloody and very offensive. On making a nasal examination the worms could be readily seen in the nose. The tissue on the middle turbinated bone had been badly injured by them. The great majority of the worms were found in the posterior nares. They had made quite a large opening in the hard palate. A solution of alcohol and water was used in the nose first. This was followed by the application of chloroform directly to the worms by cotton applicators. This remedial agent soon dislodged and brought the worms away. Hot water was used by means of a fountain syringe, and gave great relief to the patient. The patient informed me that the worms had been in his nose about two weeks. He was very weak and greatly surprised when he saw the worms taken from his nose. He was given a nutritious diet, and iron was administered. The sinuses were not involved. The patient made a rapid recovery.

Nearly every September I have a case of screw worms in the nose. In all cases of obscure nasal discharge, bloody in character, a careful nasal examination should be made. As a rule the worms can be easily seen and dislodged, much to the comfort of the patient. Occasionally the worms enter the sinuses, causing meningitis and death. I desire to thank Dr. O'Donnell, the house physician, and the sister in charge for kindly assisting in this case.

Potatoes in Diabetes Mellitus.—A. Mossé answers the mooted question as to whether potatoes may have a place in the dietary of the diabetic, in the affirmative, and cites two cases in which the wisdom of such addition to the fare was evidenced by a prompt decrease in the amount of sugar excreted in the urine. The potatoes should be given to the amount of from two to three pounds daily as a substitute for the whole or a part of the bread allowed. The cases which seem to respond best to such management are those of medium intensity and of the arthritic type.—*Klinisch-therapeutische Wochenschrift*, October 7, 1900.

Nasal Tuberculosis.—Three cases are reported by L. Bar and V. Texier. The first was a primary manifestation assuming the polypoid form, the second secondary, of granular form, and the third secondary, presenting an ulcerated polypoid condition. For treatment the authors advise the use of curetting with subsequent application of lactic acid preceded by cocainization. Scarifications may be necessary, followed by the use of iodoform in glycerin, mentholated oil, etc., with orthoform for pain. Systemic treatment must not be forgotten in these cases.—*Revue Hebdomadaire de Laryngologie*, September 29, 1900.

Heredity in Disease.—James Jamieson considers the modern tendency to minimize the influence of heredity in disease causation a happy one. The outlook becomes hopeless when we admit that disease is inherited. The change in opinion along this line is doubtless largely referable to the steady multiplication of evidence that infection plays a much larger part than was believed not long ago. It is freely admitted that a liability to disease may be inherited, though in just what this liability consists pathologists are not agreed. There may well be, there probably enough is, some delicacy of constitution, some fragility of tissue, which may be hereditarily transmitted, but that, or something tantamount to it, may be as readily acquired. Gout is always invoked as an hereditary malady; but that the son of a gouty father should with greater frequency than the average exhibit this gouty tendency, admits of at least partial explanation in the surroundings of his life, and the probability of habits of luxury or of over-indulgence among those with whom he is brought up. So if we run through the whole category of so-called hereditary diseases, and consider the matter in a broad light, we shall find that the factor of heredity is not so potent as has been believed. Jamieson admits the hereditary influence in hæmophilia, which is something more than a tendency capable of prevention or cure. In a way it is a tendency, but it is also a persistent condition born with the person, and to all appearance lasting through life, though its exact nature seems hard to settle.—*Intercolonial Medical Journal of Australia*, September 20, 1900.

The Cure of Inveterate Cases of Trigeminal Neuralgia.—C. J. Aldrich thus details his plan of treatment. The patient is put to bed under the care of a competent nurse, and receives a thorough examination of all his bodily organs and functions. The next morning he receives an initial dose of castor oil, which is ʒ i. if the patient is not taking opiates, and ʒ ii. if he has become an habitué or is temporarily using them. A solution of nitrate of strychnine is prepared, ♏ i. of which should represent gr. $\frac{1}{200}$. Of this solution he receives ♏ xx. four times a day as the initial dose, with orders that the dose should be increased one drop every twenty-four hours, being an actual increase of gr. $\frac{1}{200}$ each twenty-four hours. If the patient has been taking morphine, the least possible dose that will relieve the pain is continued for the first two or three days, after which time the dose is gradually diminished. In addition it may be necessary in cases of arteriosclerosis to give some nitroglycerin. When evidence of atheroma is present, the last-named remedy can advantageously be combined with thyroid extract. Aldrich suggests that the good effects of the castor oil may be due to the elimination of some toxic principle which acts as a nerve irritant, thus causing the neuralgia.—*Cleveland Medical Gazette*, November, 1900.

A Case of Sudden Blindness Subsequent to Cauterization of the Nose.—A. R. Baker reports the case of a man of thirty-one, in whom one week after cauterization of the turbinate pain developed within three days on the same side of the face; later a chill came on and was repeated on the third day. At the latter time there was a partial blurring of vision on the same side as the cauterization. The lower part of the visual field was gradually obliterated and in three days more the eye was totally blind. Examination showed the eye to be absolutely blind, without perception of light, the pupil moderately dilated, not responding to light or accommodation when the fellow-eye was covered. Ophthalmoscopic examination was negative. Hyperopic astigmatism of 50 D. against the rule was present. Left eye = vision Snellen $\frac{20}{40}$, increased to

$\frac{20}{20}$ with 50 D., axis 180°. The test was made under homatropine. The lower part of the field was slightly contracted. The fundus was normal. There was a large, offensive-smelling, grayish-green slough filling the right nostril, which was removed with difficulty, leaving a bleeding ulcerated surface. The patient was put on mixed treatment, though no specific history was obtainable. Under this routine the eye condition gradually improved and finally became normal. A mild condition of the same nature had shown itself in the left eye. Baker does not think that there was a gumma present anywhere.—*Cleveland Medical Gazette*, November, 1900.

Tumors of the Heart.—Alessandro Tedeschi says that the symptoms of this condition are œdema of the upper extremities, of the head, and of the chest, with dilatation of the anastomotic blood-vessels between the internal mammary and epigastric veins. These phenomena clearly indicate an obstruction to the passage of the venous blood from the superior vena cava into the right auricle—a supposition which has been confirmed at autopsy by the finding of cardiac tumors situated in the upper portion of the two auricles. These tumors frequently cause symptoms in remote parts of the body by means of emboli. In some cases a cardiac tumor has been so well tolerated by the heart that the only symptoms have been a slight systolic murmur and a slow, small pulse.—*La Riforma Medica*, October 20, 22, and 23, 1900.

Erythromelalgia Following Influenza.—Erminio Crespolani reports a case of "Weir Mitchell's disease" in a man of twenty-two years. The affection is characterized by spasmodic, burning pain, œdematous swelling of the part affected, redness, local hyperthermia, and, according to some authorities, local hyperidrosis. The author gives the various theories which are held in regard to the etiology of the disease, and leans to the view that it is due to vasomotor reflex action—probably a dilatation of the blood-vessels caused by over-excitability of the nerve centres. In the case reported, the parts affected were first the right foot and then the left. The pain was intense; the local rise of temperature increased to 3.1° C. Neither the internal use of bromides nor the topical application of the usual sedatives succeeded in relieving the pain. Tonics and cold friction of the spinal column effected a cure. The patient was obliged to keep his bed from February 11th until April 14th.—*Giornale Internazionale delle Scienze Mediche*, October 15, 1900.

The Use and Abuse of Cardiac Stimulants.—H. A. Hare calls attention to the abuse of digitalis in heart troubles, saying that in many cases of palpitation such as comes from overwork, this remedy simply aggravates the symptoms, for what the patients need is not cardiac stimulation but rest. The taking of strong coffee under these circumstances still further increases the cardiac irregularity. Very frequently the use of small doses of aconite or veratrum will effect the desired result far more quickly and efficiently than digitalis. A patient with a feeble heart receives digitalis, it may be, to overcome feebleness, when in reality the cause of the feebleness lies in a degenerated heart muscle which is incapable of gaining any advantage from this drug, and the drug by contracting the blood-vessels actually increases the labor of the heart. Under these circumstances, if any drug is used it should be one, like strophanthus or cactus, the action of which is cardiac, and but slightly if at all vascular. Not only is rest needed for the tired but otherwise healthy heart, but it is even more needful in cases in which there is cardiac breakdown, actual or threatened, in cases already suffering from grave valvular lesions. The cardiac stimulants are sometimes expected to perform miracles, although the patient pursues the same mode of life as before. This is in reality an abuse of a drug, since it is being used to do something which is practically impossible.—*Therapeutic Gazette*, October 15, 1900.

Renal Calculi, with Report of Cases.—Stuart McGuire says that his endeavor is to show that when a stone is known to exist in the kidney an operation should be done for its removal, not as a last resort to save life but as an early effort to save the organ. An early nephrolithotomy entails little risk and is not attended by mutilation; while a late nephrectomy is followed by high mortality, frequently persistent and annoying fistulæ, and the sacrifice of an important organ. The diagnosis of renal calculi is sometimes very difficult to make. Often a calculus has been found post mortem without its presence having been diagnosed, and often a kidney has been opened for suspected stone with negative results. The symptoms are due to obstruction and depend more upon the position than the size of the stone. They are pain; the passage of fragments of calculi; the presence of blood crystals, blood, and pus in the urine; frequent and urgent urination, and irregularity in the amount of urine passed, varying from anuria to marked polyuria. —*The Virginia Medical Semi-Monthly*, October 26, 1900.

Rest in Bed in the Treatment of Acute Forms of Mental Disease.—S. S. Korsakov says that in the systematic use of this form of treatment rest in bed is obtained by moral influence and suggestion rather than by violence. The use of a large room in common is of the greatest advantage. This form of treatment brings about a more orderly condition of affairs in crowded asylums, gives greater security to the patients, and allows of more accurate care and clinical observation. By its use solitary confinement in cells is rendered unnecessary except in extreme cases. Violent cases are favorably affected by rest in bed; and in asylums where it is used, the mortality percentage from acute psychoses is notably diminished. The chief indication for the treatment is excitability. In the case of patients of indolent habit, predisposed to apathy and anæmia, it is contraindicated. It is especially effectual in maniacal cases, in those suffering from alcoholic delirium, and in many forms of mental confusion and melancholy.—*Archives de Neurologie*, October, 1900.

The Management and Treatment of Whooping-Cough.—J. W. Wiltse says that Roskam's modification of Moncorvo's method would seem to be a rational procedure, and according to his statistics has succeeded well. It consists of the application to the glottis of a one-third-per-cent. solution of resorcin every four hours during the day, and when possible once or twice during the night. In a series of two hundred and ninety cases treated in this way all patients recovered. The treatment was usually begun during the catarrhal stage, though in some cases the convulsive stage had begun. Of the series two patients recovered in fourteen days. Seventy patients were cured before the end of twenty-five days and eighteen recovered within a month from the beginning of treatment. As a rule, children under one year of age recovered most rapidly, usually within eight days. This is important, as it is admitted by all writers that whooping-cough is most fatal in the very young. This method differs from Moncorvo's only in the fact that Moncorvo applied a ten-per-cent. solution of cocaine to the throat before using the resorcin. Roskam rejected the cocaine because he found it frequently caused spasm of the glottis. —*Albany Medical Annals*, October, 1900.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & CO., 51 Fifth Avenue

New York, December 22, 1900.

THE SOLDIER'S TROPICAL RATION.

IN the present conjunction of affairs, everything relating to the tropics concerns the inhabitants of the United States intimately. Thus the etiology and treatment, both preventive and remedial, of the diseases prevalent in those regions are questions of serious moment. All that can be learned with regard to the mode of life best suited to the preservation of the health of white men who make their home in tropical countries is devoured with avidity. Under existing circumstances the army in the Philippines is the focus of absorbing interest. Therefore the report of the board appointed to study the matter of tropical ration for American troops, and to suggest beneficial changes therein, will be attentively read by the general public. It goes without saying that diet is one of the most important of considerations when the rendering of a white man able to cope with his unaccustomed environment is the object in view. On this point, opinions clash. There are those who insist that under no conditions can the inhabitant of the temperate zone dwell in perfect health in tropical lands. On the other hand, many men of experience state that, if these individuals live in a manner befitting the climate, paying strict heed to the laws of hygiene, and if, above all, they are discreet in eating and drinking, there is no valid reason why they should not enjoy good health. So far as the kind of food is concerned, a wide divergence of views exists. Some argue that an entirely different dietary is indicated in tropical countries, and that the person who imagines that he can thrive on the same description of food that he eats when at home, will be certain quickly to break down. Others assert that but a slight change of diet is needed from the ordinary fare of an American in his own country, and that if the stranger in the tropics endeavors to live as does the native, he will soon lose both energy and physical power. Major Louis Seaman, late surgeon in the United States Engineers, is an upholder of the former contention, and writing to the MEDICAL RECORD says, "A personal experience in two of the latest tropical wars, and a study of the statistics of others, have led me to the conviction that the most prominent cause in bringing about the development of preventable diseases in both these wars was the misuse of food." Speaking generally, he considers that the majority of the diseases met with among troops serving in the tropics have their origin in improper food, in overfeeding, or in the abuse of stimulants; and he suggests a dietary scale containing much less meat and fat than was issued to the United States troops. Dr. Seaman is of the opinion that the ration was an excellent winter food, rich in the elements requisite for respiration under a low temperature; but for a tropical land, the enormous excess of carbon furnished by it to the lungs over and above that which they could dispose of, imposed upon the liver and kidneys additional duties of elimination, producing congestions, fermentation and catarrhs, dyspepsia and lithæmia, glycosuria and phosphaturia, interfering with metabolism, and creating conditions favorable to bacterial development, together with almost the entire train of diseases which have crowded our army hospitals. As remarked above, many medical men who have gained experience from a lengthened sojourn in the Philippines hold that meat is a necessity for the American soldier, and that, lacking it, his bodily powers will fail. The board have cautiously steered a middle course, and while recommending that the fresh-meat ration should not be reduced in quantity, declare that the problem is to find such a ration as will, by substitutes among its various ingredients, be suitable for all climates. Cornmeal has been excluded from the ration, as have dried peas, for the latter of which oatmeal has been substituted. The sugar ration, as in all European armies, has been increased, and coffee has been retained. The action of the board appears to be amply justified and will probably meet with the approval of the majority of those who have spent some time in the tropics. Fresh meat, fresh vegetables, fresh fruit, supplied in sufficient quantities, should tend to preserve the health of the dweller in tropical countries, and whenever obtainable will undoubtedly meet the exigencies of the situation better than embalmed meat and canned vegetables. Universal agreement prevails on the point that alcoholic drinks are almost invariably injurious to the white man in the tropics. It may be said that when the problem of the most healthy diet for the foreigner in the tropics is solved, the greatest obstacle in the way of rendering these countries salubrious will have been overcome.

THE AMERICAN GIRL OF TO-DAY.

THE influence of modern education on the functional development of girls is a matter the importance of which it is almost impossible to overestimate, and it is one which will bear discussion with advantage. From all sides and from all parts of the civilized world comes the cry that the vitality of the race is being sapped by injudicious methods of education. In the case of growing girls this is a question that closely concerns the physical and mental welfare of every nation, for it stands to reason that in order to produce and rear a healthy progeny, the mothers of our children should be thoroughly sound in mind and body. In the United States, perhaps to a greater extent than in any other country, has the present system

of educating girls shown its worst effects. Dr. George J. Engelmann, of Boston, dealt with this subject in his eloquent presidential address delivered before the American Gynæcological Society. Dr. Engelmann points out that the gravity of the question and the practical bearing of the results obtained are perhaps more fully apparent when we realize not only how important but how large an element of our population is concerned—374,487 young women in colleges and high schools, and over one million of the same ages in the industries. Dr. Engelmann goes on to say that "statistics have clearly shown the tremendous susceptibility and the almost feverish activity of the system in the prepubertal period, the period of developing womanhood: susceptibility indicated by heightened morbidity; nerve excitement by an increase of stuttering and hysteria; heightened physiological activity by increased growth, and resistance to disease by lowered mortality; all gradually wane as the vital energies are claimed more and more by the reproductive function, and reach their lowest ebb with the advent of puberty, again rising after menstruation is established, and it is at this period of still unstable equilibrium that we find the schoolgirl." The contention is made that the system of education in vogue in the schools and colleges of this country tends to aggravate these conditions in the rising generation of American womankind, with the result of a general and functional deterioration in health. Dr. W. Gill Wylie puts the case forcibly and well when he says that "the American horse receives, on the average, better treatment than the young woman of America from the time of early girlhood until the age of development has passed. The stock-breeder never forces the young animal during the period of development, realizing that it is the time the greatest care should be taken; while American parents, especially of the middle classes, with great ambition for their children and the desire that they develop intellectually beyond their own standard, allow their heads to be crammed with knowledge so rapidly that the brain cannot assimilate it, and the result is that all strength of development is devoted to the brain, and physique finds expansion as best it can: New England furnishing the extreme type of the woman, supposedly more perfect than in any other section; intellectually above the average, but with a physique below par, with greatly reduced reproductive powers—all due to the forcing of study at the age of development." Dr. Engelmann believes that many of the evil effects produced by this irrational mode of education may be overcome by judicious physical training and by strict adherence to the laws of hygiene. But above all he urges preventive measures, and holds that the real solution is in reasonable hours of study, in mental training adapted to physiological possibilities, and in a regard for the claims of woman's sensitive organization. The paper concludes with the following advice: "Upon the mother I would impress that perfect development of the female function, and maintenance of this function, once developed, in a healthy condition, is essential to perfect development of the girl and perfect health of the woman; that self-care, a well-regulated female hygiene, is the foundation of her well-being, and that it is the mother's first duty so to guard herself and so to guard her daughter. To the educator I would say that heed must be given the instability and susceptibility of the girl during the functional waves which permeate her entire being; that emotional stimulation must be avoided, and decided concessions must be made to the depression, physical and psychical, the lessened inhibition and physiological control during the fluctuations of puberty and menstruation. Upon the physician I would urge care and guidance of the girl during the great waves of female life, those periods of increased susceptibility, and of physiological intensification and depression; and such care is the first and essential step in preventive gynæcology." The present-day native American girl of the middle class is the artificial product of advanced civilization. She is a bundle of nerves encased in a fragile frame, and there is undoubtedly reason to fear that, unless a radical change is made in her upbringing, the consequences will be serious to the entire community. Less brain work and more fresh air and exercise are the remedies recommended.

THE INFLUENCE ON HEALTH OF THE FILTRATION PLANT AT ALBANY.

An editorial in the Medical Record of December 8th drew attention to the decreased rate of mortality in those cities in which a filtration plant had been introduced, and it was shown that a comparatively pure water supply greatly affected the occurrence of typhoid fever. Efforts are being made at the present time in several American cities of the first magnitude, as well as in some smaller ones, to curtail the spread of diseases, and especially that of typhoid fever, by insuring an unpolluted service of water for domestic purposes. The majority of experts have come to the conclusion—which is also borne out by practical proofs—that an efficient system of filtration is the best means of purifying water. The Albany filtration plant, established quite recently, is possibly the most satisfactory instance on a fairly large scale of the good results accruing from such a system in the country. In the Albany *Medical Annals* for December, Dr. Martin MacHarg, vice-president of the Medical Society of the County of Albany, contributes a well-written account of the construction and working of the newly erected filtration plant in that city. Up to September 6, 1898, when the filters were completed, Albany had been dependent, for its drinking-water, upon reservoirs supplied by small streams and upon the Hudson River. In recent years the greater portion of the water was drawn from the Hudson. Owing to the fact that the Hudson was seriously contaminated by local sewerage, as well as by the sewerage of Troy, Cohoes, and other cities, it is not surprising that the typhoid-fever death rate was excessive. Steps were therefore taken to instal an up-to-date filtration plant. Dr. MacHarg gives a description of the plant, which lack of space does not permit us to quote. Suffice it, then, to say that the methods in use are of the most

approved type. With regard to the benefits conferred upon the inhabitants by the system, Dr. MacHarg says: "The filters were designed to remove from the water the bacteria which caused disease. The superintendent of the plant, Mr. Bailey, in August last issued a report on the results of the plant for three hundred and nineteen days' actual operation, and I give his report verbatim. The number of gallons filtered was 3,817,200,000, or on an average of nearly 12,000,0000 gallons a day. This is the largest amount of water ever filtered by a single American filtration plant in so short a period. The cost of operating the filtering beds and care of the grounds has been $1.94 per 1,000,000 gallons, and that of chemical and bacteriological examination is 34 cents per 1,000,000 gallons. The cost of pumping is $2.42 per 1,000,000 gallons. The efficiency in bacterial removal has been good. As regards its removal for the first three months of 1900, the average number of bacteria in the unfiltered water for the whole plant never fell below 200 in a cubic centimetre, reaching that figure on March 30, 1900. On April 2d and 6th, respectively, when the bacteria in the raw water numbered 45,000 and 37,000 respectively, 99.07 per cent. of the total was removed. The influence upon the death rate from typhoid fever has been quick and decided. The average number of deaths from typhoid fever in Albany for nine years up to 1899 was 85 in a year. From January, 1899, to August 1, 1899, when the city was using unfiltered water, there were 71 deaths from typhoid fever; and from August 1, 1899, to January 1, 1900, or when filtered water was in use, there were only 7 deaths from this disease. From January 1st of the present year up to July 1st, there were only 19 deaths for the six months, or a total of 24 for the year, against 85, the average for the preceding years. These figures show plainly that the Albany Filtration Plant has been the most prominent factor in decreasing the death rate from typhoid fever; and the evidence from other cities and towns in which a similar system has been instituted has given equally conclusive results." Therefore it would appear that the moral to be extracted from these records by those cities which do not at present possess a filtration plant is, "Go thou and do likewise."

ADULTERATION OF FOOD.

Embalming food seems to be a universal custom, an outcome probably of advanced civilization. In Europe the practice of adding foreign substances to articles of diet —sometimes for the purpose of preserving these articles, sometimes with the aim of imitating genuine food with intent to deceive—is carried on to an alarming extent. In Great Britain, although adulteration has not reached these proportions, yet the discoveries made recently with respect to the addition of arsenic to beer prove that manufacturers there are not altogether quite innocent. The New York *Tribune*, Sunday, December 9th, contains a strong leader on the subject, taking as its text the case of an infant who, after investigation, was found to have been killed by the use of formaldehyde in the milk upon which it had been fed. The writer of the editorial referred to says: "We have no doubt that the same or a similar verdict might be rendered in the cases of tens of thousands of people, children and adults, who are literally done to death with embalmed food. The use of drugs, such as formaldehyde, boric acid, and salicylic acid, as 'preservatives is widespread to a most alarming extent.' These drugs are put into milk and cream to keep them sweet, into butter and cheese to keep them from becoming rancid, into canned fruits, and vegetable, and meats, and indeed into nearly all food products that are of a perishable nature, and that are to be kept for a length of time in which their freshness might be imperilled. They are tasteless, odorless, colorless, and their presence cannot be detected save by an expert." The article in the *Tribune* then goes on to demonstrate that the addition of drugs to food is a harmful and pernicious practice, and that the same object can be attained by natural and legitimate means. The Medical Record has ever strongly deprecated the use of drugs as preservatives of food, and has been foremost in denouncing the custom. It is scandalous that the health of the people at large, and especially of young children, should be at the mercy of manufacturers who, eager for a little more profit, have no scruples as to the manner in which it is gained. Stringent laws rigidly enforced are called for to correct this evil.

OXALURIA.

There have always been differences of opinion as to the significance of the presence of oxalic acid or oxalates in the urine, and as to whether their presence was due solely to ingestion with the food or whether it could be attributed to generation within the body. This acid occurs in many, though not all, vegetables, grains, and fruits, and is not contained in proteids and sugar. It has been found in the urine under many varied conditions, and certain vague symptoms have been associated with its presence. For the purpose of determining whether all of the oxalic acid excreted in the urine is ingested with the food, or whether any is ever formed in the animal organism by metabolism, as well as for the purpose of studying the influence of the ingestion of oxalic acid in foods upon the amount excreted in the urine, and also the physiological action of soluble oxalates, with the view of deciding in what measure the presence of oxalic acid in the system is responsible for the symptoms attributed to the so-called oxalic-acid diathesis, Dr. Helen Baldwin (*Journal of Experimental Medicine*, vol. v., No. 1, p. 27) engaged in a series of observations and experiments, as a result of which the opinion has been formed that as varying amounts of calcium oxalate may be held in solution in the urine, conclusions based upon the presence or number of calcium-oxalate crystals found therein are of no real value as an indication of the quantity of oxalic acid present. Unless the utmost care is exercised, the results obtained by quantitative estimations of oxalic acid are subject to large percentages of error. An

ordinary mixed diet regularly contains traces of oxalic acid or its salts. A portion of the oxalic acid ingested with the food may be absorbed and reappear unchanged in the urine. The normal daily excretion of oxalic acid in the urine fluctuates with the amount taken in the food, and varies from a few milligrams to two or three centigrams, being usually below ten milligrams. In health no oxalic acid, or only a trace, is formed in the body, but that present in the urine has been ingested with the food. In certain clinical disturbances sometimes associated with absence of free hydrochloric acid in the gastric juice, oxalic acid is formed in the organism as a result of fermentative activity in the alimentary canal. The prolonged feeding of dogs with excessive quantities of glucose, together with meat, leads eventually to a state of oxaluria. This experimental oxaluria is associated with a mucous gastritis and with absence of free hydrochloric acid from the gastric contents.

News of the Week.

Philadelphia Pediatric Society.—At a stated meeting held December 11th Drs. C. H. Frazier and A. L. Newhall exhibited a small colored boy in whom a pedicled flap from the buttock had been transplanted to the palm of the hand to replace a cicatrix left by a burn. Dr. C. F. Judson exhibited a child five years old presenting symptoms of "Spastic Paraplegia" following traumatism and apparently resulting from transverse myelitis. Dr. Alfred Stengel exhibited four cases of "Acute Anterior Poliomyelitis" in young children, and referred to the relatively epidemic prevalence of the disease. Dr. J. P. Crozer Griffith exhibited a case of "Nodding Spasm" in a colored child with slight symptoms of rickets. Dr. L. C. Peter exhibited a boy, about twelve years old, with a history of repeated attacks of chorea, who presented spasmodic movements of the laryngeal structures giving rise to a peculiar sound, together with other muscular movements of the type of "Spasmodic Tic." Dr. Luther exhibited also a child with weakness in the right arm and leg, increased knee jerk, staggering gait, headache, and loss of vision, with degeneration of the optic discs, probably dependent upon "Cerebellar Tumor." Drs. J. F. Schamberg and H. P. Keech reported "A Case of Acute Fatal Pemphigus," developing in a child in the sequence of vaccination. Dr. R. A. Cleeman read a paper entitled "Thirty-five Cases of Diphtheria in Private Practice Treated with Antitoxin." There were four deaths, but only one of these was directly due to the primary disease. Intubation was required in three. Comparatively large doses of the antitoxin were employed. Dr. S. Seilikovitch read a paper entitled "A Group of Symptoms; No Diagnosis." He reported the case of a child that had passed through attacks of influenza, pneumonia, and typhoid fever, and died as the result of copious hemorrhage from the mouth. There had been no symptoms of disease of the lungs, and the patient had not responded to treatment for scurvy.

The New York State Hospital for the Care of Crippled and Deformed Children, incorporated by the last legislature, is now open for the reception and treatment of patients. The hospital is located at Tarrytown, N. Y., at Paulding Avenue and the Hudson River, about a mile south of the railroad station. It has accommodations for about thirty patients. The board of managers appointed by Governor Roosevelt are the Right Rev. Henry C. Potter, Bishop of New York, President; George Blagden, Jr., Secretary and Treasurer; J. Hampden Robb, J. Adriance Bush, and Dr. Newton M. Shaffer. The hospital was established "for the care and treatment of any indigent children who may have resided in the State of New York for a period not less than one year who are crippled or deformed, or are suffering from a disease from which they are likely to become deformed." The following conditions are imposed upon all applicants: "No patient shall be received except upon satisfactory proof made to the surgeon-in-chief, by the next of kin, guardian, or a State, town or county officer, under the rules to be established by the board of managers, showing that the patient is unable to pay for private treatment. Such proof shall be by affidavit. If there was an attending physician before the patient entered the hospital, it shall be accompanied by the certificate of such physician giving the previous history and condition of the patient." Patients from three to fifteen years will be received for treatment, and all applications will be acted upon in the order of their reception. No patient will be admitted without an examination by and a certificate from the surgeon-in-chief or his assistants. No patient whose condition is such that death is likely to occur in the immediate future, or whose condition precludes a reasonable amount of relief as the result of treatment, will be admitted. Application for admission should be made to Dr. Newton M. Shaffer, surgeon-in-chief, No. 28 East 38th Street, New York, who will appoint a time and place for the examination of the patient. Patients living at remote points in the State are referred to the following gentlemen (out-of-town members of the consulting staff): Dr. A. Vander Veer and Dr. S. B. Ward, of Albany, N. Y.; Dr. Louis A. Weigel, Rochester, N. Y.; Dr. Roswell Park and Dr. Charles G. Stockton, Buffalo, N. Y.; and Dr. Richard B. Coutant, Tarrytown, N. Y.

The Samuel D. Gross Prize.—The next award of this prize, of the value of $1,000, will be made in October, 1901, no essay which the trustees deemed worthy of the prize having been received in January, 1900. The conditions are that the prize "shall be awarded every five years to the writer of the best original essay, not exceeding one hundred and fifty printed pages, octavo, in length, illustrative of some subject in surgical pathology or surgical practice, founded upon original investigations, the candidates for the prize to be American citizens." It is expressly stipulated that the competitor who receives the prize shall publish his essay in book form, and that he shall deposit one copy of the work in the Samuel D. Gross library of the Philadelphia Academy of Surgery, and

that on the title page it shall be stated that to the essay was awarded the Samuel D. Gross prize of the Philadelphia Academy of Surgery. The essays, which must be written by a single author in the English language, should be sent to the "Trustees of the Samuel D. Gross prize of the Philadelphia Academy of Surgery, care of the College of Physicians, 219 S. 13th Street, Philadelphia," on or before October 1, 1901. Each essay must be distinguished by a motto, and accompanied by a sealed envelope bearing the same motto, and containing the name and address of the writer. No envelope will be opened except that which accompanies the successful essay. The committee will return the unsuccessful essays if reclaimed by their respective writers, or their agents, within one year. The Committee reserves the right to make no award if the essays submitted are not considered worthy of the prize.

Pennsylvania State Medical Examinations.—Of three hundred and sixty-eight applicants for the license to practise medicine in the State of Pennsylvania forty-one failed to pass the necessary examination.

Typhoid Fever in South Africa.—It was stated recently, in reply to a question in Parliament, that there had been 15,625 cases of typhoid fever among the British troops in South Africa, and that of this number 3,642 proved fatal.

The Water Supply of Chicago.—We are informed that the water supply of Chicago in 1899 was equivalent to a daily per capita of one hundred and eighty-seven gallons instead of one hundred and nineteen, as stated in a recent issue.

A Woman's Hospital in Toronto.—A committee was appointed at a meeting of women held recently in Toronto to formulate plans for the maintenance of a women's hospital in connection with the Women's Medical College of Ontario. All the members of the medical staff, both attending and interne, are to be women. It is proposed to ask for twenty-five-cent subscriptions for the work from women of Ontario.

Legislation against Alcoholism in France.—A resolution has been adopted unanimously by the French chamber of deputies calling upon the government to prohibit the manufacture and sale of all alcoholic liquors pronounced "dangerous" by the Academy of Medicine. The resolution is said to be aimed especially at absinthe, the consumption of which has nearly doubled in France since 1894, and now stands at 10,000,000 litres annually.

A Veterinary Corps for the Army.—An amendment to the army bill now before congress provides for a veterinary corps, consisting of one colonel, one major, four captains, ten first lieutenants, and twenty second lieutenants. The pay of these officers will amount to $64,000 a year, besides longevity pay, allowances, and travelling-expenses. At present there are thirty-four veterinarians in the army. Fourteen of these are sergeants, one being attached to each field battery. Twenty are commissioned officers known as senior and junior "veterinarians," one of each grade being attached to each of the ten cavalry regiments.

Pathological Society of Philadelphia.—At a stated meeting held December 13th a general exhibition of card specimens was made and proved most interesting and successful.

The British Congress of Tuberculosis will be held in London during the week beginning July 22, 1901, under the auspices of the National Association for the Prevention of Consumption. The president of the executive committee of the congress is Dr. T. Clifford Allbutt and the general secretary is Mr. Malcolm Morris. The congress will be opened by the Prince of Wales. There will be four sections on state medicine, pathology, human medicine, and veterinary medicine respectively. The section meetings will be held in the forenoons and the general sessions in the afternoons. Foreign governments and universities will be invited to send delegates.

Cornell Medical College Building in Ithaca.—The executive committee of the board of trustees of Cornell University has awarded the contract for a building for the use of the medical department on Cornell campus. The building will cost $125,000, and when finished will, it is said, be the handsomest on the campus. The building will be situated next to the College of Law, and will nearly complete the large quadrangle of university buildings. The contract calls for the completion of the work so that the building will be ready for occupancy in the autumn of 1902.

Philadelphia County Medical Society.—At a stated meeting held December 12th Dr. Ernest Laplace exhibited a young man from whom he had removed a neuroma of the ulnar nerve resulting from traumatism, with almost immediate restoration of motility and sensibility. Dr. John C. Munro, of Boston, read by invitation a paper entitled "Lymphatic and Portal Infection Following Appendicitis." The discussion was participated in by Drs. H. A. Hare, Edward Martin, John B. Roberts, John G. Clark, Simon Flexner, M. H. Fussell, Mordecai Price, T. S. K. Morton, and G. E. Shoemaker.

Sanitation in Havana.—Some of the residents of Havana are getting uneasy over the work of the sanitary authorities and are complaining bitterly of the new order of things. We learn from *The Sun* that a meeting of three hundred householders and tenants was held in Havana last Sunday, under the auspices of the Havana Union of Property Holders, to protest against the sanitary department. Various house owners who addressed the meeting declared that the sanitary department had no definite plan, and that it often issued unnecessary and even impossible orders (such as to connect the houses with the street drains when the streets had no drains), the householders then being heavily fined for not obeying. The meeting resolved to name a committee to explain to Governor-General Wood the cause of the discontent, and to ask him to define all the requisites which householders must fulfil in order that they might know how they stood within the law. They will also ask that the sanitary depart-

ment be abolished. Some of the speakers asserted that many of the changes made in houses resulted only in profit to the contractors who furnish the labor and material. The sanitary department may, as these complainants assert, have occasionally been somewhat arbitrary in its provisions, but that it has on the whole been productive of an enormous improvement in the health conditions of the city no one, except those who have to pay for making their houses clean, will deny. Major Gorgas in his report for November states that the number of deaths during that month was only 444, which is the smallest number of deaths for any one month in the past ten years. "The mortality records," he says, "show a steady and rapid improvement in the sanitary condition of the city, and the death rate of this month, 21.31, will compare very favorably with that of many of the large cities of the world. Munich with 23.09, St. Petersburg with 25.02, Dublin with 30.08, and several other large centres in Europe, had a very much larger death rate for the year 1899 than we had during the month of November." While the general sanitary conditions show such marked evidence of improvement, the number of yellow-fever cases has been large for the time of the year. The total for the month was 214 cases, or one-third less than it was for October, and, from the rapid way in which it is decreasing, Dr. Gorgas thinks that it will disappear by the middle of December. If that proves to be the case, the congress will have been unnecessarily postponed. The idea of a body of medical men postponing a meeting through fear of disease has already been the occasion of some gentle banter on the part of the unthinking laity, and if there should be no disease after all, then the banter might become ridicule.

College of Physicians of Philadelphia, Section on General Medicine.—At a stated meeting held December 10th Dr. F. A. Packard exhibited "A Case of Probable Localized Interlobar Pleurisy." Dr. D. J. Milton Miller reported "A Case of Malignant Endocarditis with Extensive Vegetations on the Pulmonary Valves Alone, and he exhibited the heart. Dr. J. Dutton Steele read a paper entitled "The Association of Chronic Jaundice with Gastroptosis, with the Report of a Case and the Exhibition of the Patient." Dr. F. A. Packard exhibited an enlarged liver and a greatly distended gall bladder containing calculi from a case presenting during life symptoms of ball-valve calculus of the gall bladder.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the navy for the week ending December 15, 1900. December 7th.—Pharmacist J. F. Pearson ordered to the naval academy. December 10th.—Assistant Surgeon J. C. Pryor detached from the *Albatross* on reporting of relief and ordered home to wait orders. Assistant Surgeon C. S. Butler detached from the *Independence* and ordered to the *Albatross*. Assistant Surgeon J. B. Dennis detached from the *Wheeling* on reporting of relief and ordered home and to wait orders. Assistant Surgeon C. N. Fiske detached from the naval hospital, Mare Island, Cal., and ordered to the *Wheeling*. December 13th.—Passed Assisttan Surgeon W. M. Wheeler detached from the *Kearsarge* and ordered to the *Alabama*. Passed Assistant Surgeon T. W. Richards detached from the *Alabama* and ordered to the Bureau of Medicine and Surgery, navy department. Passed Assistant Surgeon F. L. Pleadwell detached from the Bureau of Medicine and Surgery and ordered to the *Kearsarge*.

Philadelphia Association of Medical Inspectors of Schools.—The medical inspectors of the Schools of Philadelphia have formed a permanent organization for the purpose of raising to the highest standard the service rendered. Meetings are to be held monthly, when papers will be read and topics having relation to school hygiene will be discussed. The work of the inspectors has thus far been voluntary and gratuitous, but it is hoped that an appropriation will be made sufficient to yield each a nominal honorarium.

Influenza is reported to be prevailing to an unusual degree in Berlin.

Smallpox Cases are still found nearly every day in the city, but most of them can be traced to the original focus of infection, and the threatened epidemic is wholly under control by the board of health. A case was reported in Jersey City last week and according to the daily papers was the third case that has come to the notice of the health authorities in that city in four years.

Obituary Notes.—Dr. William K. Jones died of diabetes at Bethlehem, Pa., on December 13th, at the age of sixty years. He was graduated from the medical department of the University of Pennsylvania in 1863 and was appointed acting assistant surgeon in the United States navy, becoming passed assistant surgeon three years later. In 1873 he was commissioned surgeon and in 1891 medical inspector, being retired in 1893.

Dr. Leroy J. Brooks, of Norwich, N. Y., died on December 12th. He was a graduate of the Bellevue Hospital Medical College in the class of 1872. He was a prominent member of the Chenango County (N. Y.) Medical Society, which body met in special session on the day of his funeral and adopted resolutions of regret and of sympathy with the family of the deceased.

Dr. James Fleury Stewart died on December 11th at the S. R. Smith Infirmary, at New Brighton, S. I., where he was resident physician. He was twenty-three years of age.

Dr. Henry Barton Fellows, a homœopathic physician of Chicago and at one time dean of the Hahnemann Medical College in that city, died on December 16th at the age of sixty-three years. He was a graduate of the Homœopathic Hospital College of Cleveland, Ohio, in the class of 1861.

Dr. John C. Acheson died at his home in this city on December 12th, of valvular heart disease. He was born here in 1832 and was graduated from the College of Physicians and Surgeons in 1859. He was one of the founders of the Medical Association of Greater New York.

Progress of Medical Science.

Medical News, December 15, 1900.

Influenza and the Nervous System. — J. M. Mosher concludes that: (1) The infection of influenza produces a toxin, which has a severe and selective action upon the nervous system. (2) The immediate effects of this toxin are shown in affections of the peripheral nerves and the cerebro-spinal centres. (3) The remote effects are manifested in lowered tone of the nervous system, predisposing to other diseases. (4) These ensuing diseases arise in weakened or predisposed organs, giving rise to the different classes of "respiratory," "alimentary," "genito-urinary," and "circulatory" forms of influenza. (5) Post-influenzal insanities are also a complication of the post-influenzal states of nervous debility, in patients mentally predisposed. (6) The post-influenzal insanities are not essentially different from other insanities due to vital depression. (7) The prognosis of influenzal affections is generally good, under proper management. (8) Exception to this is in influenzal affections arising during the course of other severe diseases, as pneumonia and general paralysis, and during senility complicated by mental or physical deterioration.

The Clinical Picture of Epidemic Influenza.—Glentworth R. Butler declares that the symptomatology of this disease is extraordinarily diverse. The attack is generally ushered in by chilliness or rigor. Fever is nearly always present. As a rule there are severe headache and general aching, with weakness and prostration. Delirium is not uncommon. Dependent upon the special localization of the infection, certain varieties of the disease with their attendant symptoms are recognized, viz., the respiratory form, the nervous form, etc. Circulatory symptoms are common. The nervous system is affected to some extent in all cases. The spleen may enlarge acutely. Acute nephritis is not rare. Vertigo is not infrequently observed. Herpes labialis is common. In doubtful cases a bacteriological examination is valuable. The disease may require differentiation from typhoid fever, cerebro-spinal meningitis, and broncho-pneumonia. Recovery occurs in the large majority of cases.

A Note Concerning the Treatment of Influenza by the Employment of Hydrotherapy.—E. L. Shurley states that the first therapeutic indication should be to assist nature in the elimination of the infection and in the modification of the action on the ganglionic nervous system. The hot-water bath, steam bath, or hot pack with quinine and mild anodynes should be used at first. When the temperature is very high, the cold pack should be used instead of the hot baths. Especially for pain tinctura opii camphorata or opium may be given. To relieve debility and nervousness, following the first stage, phosphorus (gr. $\frac{1}{100}$) in capsule, in oil, is good. Strychnine is useful. Complications and sequelæ must be treated according to the circumstances of the case. The employment of the coal-tar products is as a rule inadvisable.

The Journal of the Amer. Medical Ass'n, Dec. 15, 1900.

Ear Diseases in Infancy and Childhood.—J. Homer Coulter states that the ear conditions most often met with in infancy and childhood are acute middle-ear suppuration with or without its complications—impacted cerumen, foreign bodies, furunculosis, granulations, eczema, necrosis, polypi, meningitis, extradural abscess, cerebral abscess, and traumatisms. The main causes of ear troubles in children are: (1) General, as exposure, climatic influences, etc. (2) Exanthemata, typhoid, diphtheria, post-nasal pathologies, etc. (3) Traumatisms and foreign bodies in the tympanic cavity. The prognosis will depend on the following conditions: (1) The age and physical condition of the child. (2) The severity of the attack and, if purulent, on the seriousness of the concomitant disease which gives rise to the purulency. (3) Whether or not there be brain or sinus involvement pending or threatened. (4) The extent of bone necrosis present when first seen. (5) Nursing. As to treatment, the earlier it is instituted the better. The use of opium in earache is rarely or never to be advised. The application of heat or cold will usually give quite as much relief from the pain. If this method does not greatly relieve the suffering in twenty-four hours, then heroic measures must be adopted. Usually there will by such time be indications sufficient to warrant a paracentesis. That such operation should be done as soon as there is any bulging noted in the tympanum, is now the unanimous verdict of otologists. Many authorities advise the use of leeches to deplete the congestion. Politzerization in any of the ear diseases of childhood is impracticable in almost every conceivable case. So also, as a rule, is the application of poultices. The pathological conditions of the nasopharynx and pharynx should always be thoroughly treated. The diet should be limited and mild. Early and thorough cleansing and antisepsis are always a necessity.

Treatment of Skin Cancers without Operation.—Henry W. Stelwagon is convinced that for the more superficial skin cancers the treatment by the caustic method is equal and in many cases superior to operation. Irrespective of the natural objections of many patients to operative measures, he believes that the caustic method, properly followed out, lessens the chances of recurrence. There is no damage done with caustics if they are judiciously and boldly used; it is the temporizing treatment with mild caustics, or the hesitating treatment with active caustics, which may often do harm. The caustics which the writer has found most useful are: Arsenious acid, caustic potash, zinc chloride, and pyrogallol. The first three are most commonly used, the most valuable being arsenious acid. Pyrogallol and arsenious acid have practically an elective action, destroying the pathological tissues, and having, when properly employed and not too long applied, but little influence on healthy structures. The writer has never seen toxic absorption from the cautious use of arsenic. The arsenious acid is made into a paste with mucilage acacia by mixing with a little water or a solution of cocaine hydrochlorate which somewhat lessens the pain of application. The writer also describes the methods of application of each of the four caustics mentioned in the beginning.

Tænia Flavopunctata.—Frederick A. Packard describes a parasite taken from a Syrian woman aged forty years. One specimen was passed during life and another was taken from the intestine after death; the latter was 27 cm. long and different from the former specimen in no way except by the presence of the head and of a short neck, and by its color. The specimen passed during life was brownish-yellow, while that found at autopsy was almost pure white with a faint yellow tinge. This specimen consists of a head and a short neck separated by a slight constriction, and of a segmented body. The head is black at the tip, the pigment being arranged somewhat like the leaves of a four-leaf clover, as though each division represented the sucking-discs seen in other tænia. No distinct cupping is visible. At a distance of 1.5 cm. from the head, distinct transverse striations are seen which evidently indicate division into proglottides. There is no branched arrangement of the egg-sacs nor any central clumping as in the bothriocephalus latus. This cannot be a tænia common to this part of the world, nor is it an example of bothriocephalus. It must, the writer believes, be a specimen of tænia flavopunctata which has been described but six times as occurring in the human subject.

Treatment of Immature Cataract.—John E. Weeks, after speaking of general and local therapeutic measures in respect to cataract, reviews the operative procedures for the removal of immature cataract as follows: In young individuals, needling of the lens, with or without subsequent extraction of the broken-up lens substance, by means of small linear incision in the cornea; preliminary iridectomy, with or without direct or indirect trituration of the lens, for the purpose of hastening the maturity of the cataract, applicable to old or young individuals; extraction either simple or combined. The ripening operations have been abandoned by the writer. Whenever, in the development of cataract, the vision is reduced to such a degree that the individual cannot follow the ordinary pursuits of life, provided there is any reason for not waiting until the cataract is mature, he does not hesitate to advise operation.

New York Medical Journal, December 15, 1900.

Derangements of the Organs of Vision which may be Attributed to Auto-infection, or to Auto-intoxication.—J. H. Woodward's headings of this subject are functional derangements (neurasthenia and migraine) and organic derangements (rheumatism, Bright's disease, and intra-ocular hemorrhage). In neurastheuic cases we find imperfect gastric and intestinal digestion with constipation and a sluggish liver. These patients complain of blurring of vision, lacrymation, photophobia, inability to read without pain in the eyes, etc. As soon as the primæ viæ are regulated, the ocular disturbances disappear. A similar line of reasoning applies to migraine and the other bodily states mentioned. The importance of the matter lies in the proper recognition of the underlying cause in each individual case.

The Prevention of Nausea and Vomiting during Anæsthesia.—L. J. Hirschman advocates the use of a new preparation called chloretone, which is in general a hypnotic, antiseptic, and analgesic. It is given in doses of from gr. x. to xv. half an hour before the anæsthetic is administered. From an experience with sixty cases, half of which received the drug, while half did not, the claim is made that nausea and vomiting were seventy per cent. less in the former group than in the latter.

Venesection in Pneumonia followed by Injection of Normal Salt Solution.—William Porter, in treating this subject, refers to the lobar or so-called croupous inflammation. In the experiments which he reviews, venesection is ordered as soon as the diagnosis is well established, *i.e.*, within four days, at farthest, from the initial chill, and generally earlier. The amount of blood removed is not necessarily large. From eight to ten ounces will generally give relief in average cases. At once the subcutaneous injection of the salt solution is ordered. Transfusion could be performed in an urgent case. The following solution is useful:

℞ Sodium chloride	gr.	30
Potassium chlorate	"	60
Sodium sulphate	"	60
Sodium phosphate	"	40
Sodium ca bonate	"	60
Distilled water to make	f℥	6

One piut of this solution in sixty of distilled water.

The writer hopes that further investigation may justify this method as an addition to our treatment in pneumonia.

The Electrical Treatment of Uterine Fibroids.—Gideon C. Segur concludes that: (1) Electricity properly applied may be considered a specific for the treatment of uterine fibroids. (2) A moderate dosage, 40 to 50 milliamperes, applied for twenty to thirty minutes relieves pain and influences a diminution in size. (3) There are no dangers to be feared from its use if carefully conducted. (4) Puncture is not necessary in order to obtain practical results. (5) No serious operation should be undertaken until after electricity has been tried.

Clinical Lectures on the Causes and Cure of Insomnia.—Sir James Sawyer declares that hypnotics should be given only in exceptional cases and only when unavoidable. As a rule the successful treatment of a case of sleeplessness follows from the discovery of its cause. In the severer forms of psychic insomnia sleep must often be secured by the action of some efficient hypnotic, of which opium and chloral are to be preferred. A few nights of good sleep will do more than anything else to restore to the brain the power of sleeping without further aid from drugs. A patient should never be allowed to dose himself with hypnotics. An overworked man or woman must never be permitted to go on with overwork and habitually secure sleep by chloral or any other hypnotic. It is mostly worry, not overwork, or it is work under wrong conditions, which brings unrest. When a drug is necessary, potassium bromide is by far the best hypnotic in well-nourished patients and in the slighter cases generally. It is marvellously powerful in producing nervous calm; it is a direct and quite safe brain sedative. After getting into bed, gr. xxx. to lx. dissolved in water should be the dose. In many cases of chronic wakefulness arising from prolonged mental strain, the patient is distinctly anæmic. This patient needs hæmatinics, of which the best are iron and arsenic, singly or combined. The diet must be generous, containing plenty of fish, meat, and eggs. For such a patient alcohol is often the best hypnotic. Alcohol is the best hypnotic in many cases of chronic psychic insomnia when the patient is worried and weakly, sorrowful and anæmic. A bicycle, a horse's back, gardening in the open air, muscular exercise of various kinds—all have a place in the cure of insomnia. Sunshine is a valuable adjuvant in the cure of insomnia. Monotonous counting has been suggested. Deep inspirations often help to induce sleep. Bedclothes should be sufficient, but not excessive. In all cases the bedroom window should be open all night and all the year round, but so arranged that there be no draught. A hair mattress is the best bed. In some cases a little food taken just at the time for sleeping is an efficient soporific. In the toxic kinds of insomnia the consumption of the disturbing tobacco, tea, etc., must be lessened or stopped. Senile insomnia is very obstinate. Perhaps the bromides, with full doses of hop or henbane, are the most efficient remedies in these cases.

Remarks on the Diagnosis and Treatment of Arsenical Neuritis.—Judson S. Bury, in speaking of the recent epidemic, points out several symptoms which serve to diagnosticate arsenical neuritis: Hyperæsthesia of the skin and muscles, although common in alcoholic neuritis, is more constant and generally more severe in the cases now under observation. Erythromelalgia. — The vasomotor phenomena which characterize the condition known by this name, while only occasionally present in alcoholic cases, have been conspicuous features in the present epidemic. Ataxia has been comparatively frequent in the present series of cases. There seems to be no evidence that arsenic directly attacks the muscular tissue of the heart. Psychical disturbances in arsenical neuritis are mentioned by several authorities. The first step in the treatment is removal of the cause. Next, rest in bed is advisable. A water-bed affords great comfort. The patient should be handled as gently as possible. The limbs should never be massaged. Warm fomentations are indicated for the relief of tender nerves and muscles. Salicylate of sodium and potassium iodide are of great service in the early stages. Antipyrin, phenacetin, or exalgin are efficacious in the presence of neuralgic pains. Strychnine must not be given in the acute stage. Diet is of more importance than are drugs and should consist of boiled milk, beef tea, beef extracts, soups, and broths. Nutrient enemas should be administered when vomiting is troublesome. Complete rest in bed in a well-ventilated room, careful feeding, and exposure to sunlight are the essential points in the treatment of the early stages of multiple neuritis. When the acute symptoms have subsided, but not before, recourse may be had to massage, electricity, and tonic treatment. Of all drugs tending to the restitution of the paralyzed parts, strychnine is unquestionably the most valuable.

Foreign Body Long Retained in the External Auditory Meatus.—William L. Cullen reports the case of a lady aged seventy-eight years, who had complained for thirty years of deafness in her left ear. The ear was syringed, and after one or two large pieces of hardened wax had come away, a small round ball about the size of a pea was discharged. This proved to be a piece of tortoise shell which had broken off from a comb she had worn thirty years previously. After using Politzer's bag twice, the hearing was almost normal in the ear in question.

Dislocation of the Styloid Process.—Wyatt Wingrave calls attention to the existence of the subpharyngeal cartilage of Luschka, which is probably often mistaken for a

displaced styloid process. It consists of hyaline cartilage embedded in a capsule of white fibrous tissue, and is supposed to be a vestige of the third post-oral arch. It sometimes offers an exceptional resistance to the guillotine.

French Journals.

Hygiene of the Cyclist.—Just Lucas-Championnière states that cycling, like all exercise, should be taken up moderately. The heart should be carefully watched, not because this exercise is more harmful in this respect than others, but because it can be indulged in much longer without giving a sense of fatigue. Vicious attitudes, such as a crooked posture, although not being so important as is generally supposed, nevertheless, ought to be avoided. In a long journey the position in which the body is moderately inclined is best for the organs of respiration and circulation. The position in the saddle is hard to decide upon for every case. Practice shows that the perineum accommodates itself to the saddle better than would have been supposed. Moderation in eating is a necessity in muscular work, as is also abstention from alcohol. The bicycle should vary in details for the man, the woman, the child, the racer, and the invalid. In the case of a man, the perineum, with its component parts, should be carefully watched. As to the woman, this exercise is easier for her than for the man, since she is more supple. • It causes far less fatigue than walking. Its effects on the pelvic organs are good. The exercise should be suspended during menstruation, and it is not to be recommended during pregnancy. The child does not feel so much fatigue as the adult, but it should use the bicycle with the greatest moderation. As a rule the courier understands his limitations well. He should, like all athletes, possess perfect organs. As to the invalid, many ailments are improved or even cured by the use of the bicycle, *e.g.*, gastro-intestinal troubles, deformities of the vertebral column, etc. Indeed, the author believes that this branch of the subject is so extensive as to deserve a special chapter.—*Gazette Médicale de Strasbourg*, November 1, 1900.

Foreign Bodies in the Orbit.—Paul Boudin, in reviewing this subject, says that no classification of foreign bodies that have been found in the orbit could be really complete since the variety is so very great. Bits of lead, fragments of wood, needles, bits of stone, bits of glass, pencils, metal tips, umbrellas, etc., are found in the list. As to the symptoms, there is no real pathognomonic sign of the affection. It is really remarkable how many cases there are in which no clear symptoms of inflammation are seen. Recently radiography has proved an efficient aid in diagnosis. By this method it is possible to determine the presence of the foreign body, its form, and its position. As a general rule extraction should be advised if the wound is recent, the foreign body visible, tangible, easily accessible, and if it is retained in the orbital cavity without affecting the walls. As to the use of the magnet, although it has been successful when the body was superficial, it has failed when the object to be extracted was either deeply or firmly fixed. Treatment of foreign bodies in the orbit should depend entirely on the symptoms which tell whether the physician may temporize or not.—*Gazette des Hôpitaux*, November 17, 1900.

Seborrhœic Eczema of Unna.—Léon Perrin declares that Unna with his conception of eczema has revolutionized all ancient dermatology. For him the majority of eczemas are seborrhœic. Seborrhœic eczema is the type of eczema. Wherever the eczema may be found the extension of seborrhœic eczema in the adult and in the nursling has a certain number of common characteristics: (1) A centrifugal extension in discs and circles. (2) A yellowish coloration that is frequently seen after it is healed. (3) Three varieties of lesions: (*a*) Squamous, in which inflammation is very slight; (*b*) erythematous with crusts; (*c*) humid and oozing, frequent in children and women. (4) The odor of the discharge; the thickness, the yellow color, the friability, and the oily condition of the scales. As to the therapeutic agents for this affection, preparations with a base of sulphur, salicylic acid, resorcin, oil of cade, etc., form the basis of treatment. The individual who has once suffered with seborrhœic eczema should observe extreme precautions in external antisepsis and cleanliness.—*Gazette des Hôpitaux*, November 15, 1900.

The Relation of Leucoplakia Buccalis to Syphilis and Cancer.—Alfred Fournier concludes that: (1) Leucoplakia is an affection confined almost exclusively to the masculine sex (three hundred and nineteen cases out of three hundred and twenty-four). (2) The two principal etiological factors are syphilis and tobacco. (3) It ends in buccal cancer with a frequency greater than thirty per cent. (4) When it is found in syphilitic subjects, it proves absolutely refractory to treatment said to be specific for syphilis. (5) Its pathological classification would place it among the parasyphilitic affections. (6) Finally, it makes a great difference in the prognosis of syphilis since so many syphilitics die of buccal cancer through the intervention of leucoplakia.—*Gazette Hebdomadaire*, November 15, 1900.

Two Cases of Intestinal Occlusion by Cancer of the Colon.—Victor Pauchet concludes after reviewing these two cases that when there exists an acute intestinal occlusion from cancer of the colon, if the intestinal coils are very much distended and conditions for relief are not favorable, and if the general condition of the patient permits, an artificial anus should be established. This will be only a temporary condition, for some weeks later the cancerous segment can be treated and the artificial opening can be closed.—*Gazette des Hôpitaux*, November 13, 1900.

Münchener medicinische Wochenschrift, Nov. 27, 1900.

Observations on Suicide Based on Three Hundred Autopsies.—Arnold Heller draws some interesting conclusions from a careful analysis of the results of three hundred autopsies on suicides. The fallacy of the belief current in professional as well as lay circles, that such individuals are usually subjects of some definite mental disease, is shown by the fact that this was found in only five per cent. of the cases. A more important observation, however, is that nearly one-half of the subjects, at the time the act was committed, were in such a state of disturbed mental equilibrium as to be unable to resist impulses which would ordinarily have left them unaffected. More exactly stated, it was found that forty-three per cent. were in such a condition, owing to the early stages of unrecognized acute infectious diseases, the menstrual epoch, pregnancy, etc., as to be temporarily incapable of sound judgment, without being the victims of any actual mental disease. The significance of such a result may be realized when it is considered that this really means that nearly fifty per cent. of these three hundred cases were not true suicides at all in the sense so severely condemned by sociologists and moralists, since the act was performed at a time when the individual was not responsible for his actions, and the inference is that a careful post-mortem examination should be made by competent pathologists in every case of supposed suicide before it is pronounced as such, with the consequent stigma on the descendants, loss of insurance, etc.

Hereditary Progressive Spinal Muscular Atrophy in Childhood.—J. Hoffmann describes a disease of which he has seen six cases and of which the essentials may be summed up as follows: The patients are children of good parentage and usually between the ages of five and nine months. The first symptom is a symmetrical, atrophic, slowly progressive paralysis of the muscles of the thigh and pelvis, shown by cessation of the natural kicking and attempts at crawling and standing. The process gradually invades the musculature of the back, abdomen, neck, and shoulder girdle, involving both upper and lower extremities in a descending palsy to their very tips. At the same time the reaction of degeneration and absence of the tendon reflexes are noted, together with obesity and, ultimately, contractures. The sensory system is unaffected, the organs of special sense functionate normally, and muscular hypertrophy or pseudo-hypertrophy is absent. The disease always terminates fatally in from one to four years after its onset, death being due to secondary pulmonary infections.

The Atropine Treatment of Intestinal Obstruction.—By Lüttgen. The results of other advocates of this method of dealing with intestinal obstruction have already been reported in abstract in this journal and the observations of the above writers confirm the favorable conclusions of their predecessors. Of the four cases they detail, recovery followed in three, and was undoubtedly due to the atropine injection, and though the fourth terminated fatally the medical treatment was not resorted to until after operation had failed to relieve. The dose employed is the huge one of 0.005 gm. (gr. $\frac{1}{12}$), but toxic symptoms were noted in only one instance and then soon subsided, while happy results have now been reported in so many cases as to justify a trial of the method whenever operation is contraindicated or refused.

A Practical Method of Increasing the Digestibility of Cow's Milk.—The process suggested by v. Dungern consists in raising the previously sterilized milk to the body temperature and precipitating the casein with lab ferment. The resulting curds may now be easily subdivided by agitation or churning until they remain suspended as fine flakes which resemble the coagula produced in human milk. By this means the chief factor in making cow's milk less digestible than breast milk, viz., the large and tough casein clots formed on contact with the gastric juice, is eliminated, while experiment has shown that milk so prepared is just as readily taken and retained as when given in the usual way.

The Value of the Serum Reaction in the Early Diagnosis of Tuberculosis.—Arloing and Courmont publish a refutation of the conclusions drawn by Beck and Rabinowitsch in a recent number of the same journal, which reflected on the utility of the serum reaction, to which the names of the first two authors are now attached. The discrepancies of the results obtained by the later observers are attributed to differences in technique, and the authors adhere to their former dicta that (1) in tuberculous subjects agglutination takes place at a dilution of from 1 : 5 to 1 : 20 or even higher. (2) The reaction is most marked in light cases and may even fail completely in advanced stages. (3) The diagnosis of tuberculosis by means of the serum reaction seems adapted, on account of its quickness and harmlessness, to win clinical consideration in spite of the technical difficulties its performance presents.

The Treatment of Heart Disease.—H. Hellendall's device consists of a truss having a pad controlled by a spring and designed to support the apex beat. Not all cases derive benefit from this apparatus; out of ten it was found inapplicable in two, viz., one of aortic insufficiency and one of aortic aneurism. In the others, which comprised exophthalmic goitre, neurasthenia, mitral and aortic incompetence, and secondary hypertrophy, the beneficial effect was very great in reducing the tendency to palpitation and relieving the sense of oppression and dyspnœa on exertion.

Berliner klinische Wochenschrift, No. 47, Nov. 19, 1900.

Symptomatology of Facial Paralysis.—By M. Bernhardt. Details are given of a series of cases differing somewhat from the classical type. They show that cases due to peripheral lesion exist, in which there is no reaction of degeneration, but in which the muscles react instantly to the electric stimulus; in addition there are cases, probably congenital, in which are contractions on the affected side of the muscles in the vicinity of the middle line of the chin and lower lip from the crossing over of exempt fibres from the normal side. Finally, there are cases congenital or occurring in early years, which show this peculiarity that irritation with currents so weak that no contraction results on the sound side, causes a lessened irritability of the affected side.

Woman's Milk.—M. Cohn has examined many specimens of human milk under various conditions of lactation and finds therein certain elements which he suggests may possibly be the cause of infantile dyspepsia.

Fœtal and Infantile Typhoid.—John Lovett Morse says that, except for the lessened exposure in the first year through food, there seems no obvious reason why typhoid should be less frequent in infancy than in later life. Nevertheless, judging from the small number of cases reported, it is less frequent. As to fœtal typhoid, the bacillus can traverse the abnormal, and possibly the normal, placenta from mother to fœtus, and infection of the fœtus results. The fœtus as a result usually dies in utero or at birth, or it may possibly live a few days. Intrauterine typhoid is, from the first, a general septicæmia. Classical lesions of typhoid are wanting. Infection does not always occur, the pregnant woman not necessarily transmitting the disease to her child. The serum reaction occurs in infantile as in adult typhoid. There are no data as to whether or not it occurs in fœtal typhoid.

Pulmonary Tuberculosis in Infants and Children.—Frank P. Norbury holds that this disease is not a rarity among children. It may occur by direct hereditary transmission, but is more likely to be due to infection from a tuberculous mother. Milk is also a source of infection. The child of a tuberculous mother should be artificially fed with sterilized milk, should sleep in a room apart from its mother, and kissing by her should be prohibited. To the child afflicted with the disease, the open-air treatment is the best, the most suitable, and the most satisfactory. Knopf says, "Children and young people often develop tuberculosis for no other reason than that they are naturally bad eaters." Hence wholesome food, plenty of it, at proper intervals should be given. Raw eggs are good. Children often acquire a real liking for pure Norwegian cod-liver oil. The weight of the patient is the best guide for us in determining the benefits of treatment.

A Report of One Hundred and Eighty-seven Cases of Measles with Reference to Koplik's Spots, and their Value in Diagnosis.—John I. Cotter gives the following figures as the results of the observations made: Koplik's spots—positive, one hundred and sixty-nine cases; negative, eight; doubtful, ten. Of the entire one hundred and eighty-seven cases not a single one presented Koplik's spots as the only evidence of the disease which was to follow. Other evidence regularly presented was a rise of temperature to more than 99° F. The authors were unable to diagnose a single case on the strength of the spots alone, because the two symptoms, fever and spots, travelled together invariably. However, it is not known that any disease other than measles presents these spots, and their value in diagnosis should meet with the universal appreciation which their importance demands.

Fatal Intestinal Hemorrhage without Known Cause in an Infant of Five Months.—By Maurice Ostheimer.

Poisoning by Vapo-Cresolene.—By S. S. Adams.

Annals of Surgery, December, 1900.

Structure, Fracture, and Refracture of the Patella.—E. M. Corner states that the patella is peculiar in that when submitted to direct violence the femur acts as an anvil and it is violently compressed between the "hammer" and the "anvil." Under such circumstances a stellate fracture results. In two directions the above must be modified, viz., the extent of the areas over which the direct violence is diffused or applied, and the relations of the size of the "force-areas" to that of the "contact-areas" between the patella and the femur. To deal with the first of these, it may be stated that the greater the "force-area" the greater the likelihood of stellate fracture and comminution, and *vice versa*. With regard to the second, if the force-area equals or is greater than the contact-area, a stellate fracture will probably result. If, on the other hand, the force-area is less than the contact-area, a transverse or oblique fracture may result, and the smaller the force-area the more likely is this result to be attained. Such an accident as the last is of rare occurrence. From a study of one hundred and ninety-one cases occurring during nine years and treated at St. Thomas' Hospital, Corner finds that in transverse fractures the upper fragment was the larger in 37.7 per cent., the line of fracture about at the centre in 45.5 per cent., and the lower fragment the larger in 16.8 per cent. Hence the lower half of the bone is more often broken than the upper, and this is accounted for by the fact that anatomically this lower half is weaker in structure. He believes that one of the reasons for the failure of ossification to extend into even short fibrous unions is the fact that the patella is a sesamoid bone; it differs from other bones in that it is not surrounded by a periosteum. In consequence of this, the osteogenetic powers must be comparatively small, and so bony union will not occur unless there is close approximation of the fragments.

The Radical Cure of Inguinal Hernia in the Female.—W. B. Coley has employed in one hundred and twenty-three cases a method of operation which is practically Bassini's method as performed in the male, the single step of transplanting the cord being omitted. The incision is made one-half to three-fourths of an inch above and parallel to Poupart's ligament, and should extend nearly to the level of the anterior superior spine. The aponeurosis of the ex-

ternal oblique is slit up well over the internal ring and dissected back to the edge of the rectus on the inner side and on the outer sufficiently far to expose the thick fold of Poupart's ligament. If the sac is sought for high up just below the edge of the internal oblique muscle, there will be no difficulty in finding it. After the sac has been dissected from the round ligament and thoroughly freed well within the external ring, it is transfixed and tied off with catgut. The wound is then closed in three layers, as in Bassini's method, a medium-sized kangaroo tendon being used for all buried sutures and catgut for the skin. In the deep layer, interrupted sutures, usually four or five in number, are introduced from above downward, bringing the internal oblique and transversalis muscle over to Poupart's ligament. The round ligament is allowed to drop back into the lower angle of the wound, and as it approaches the pubic bone it is so small that it requires much less space than the cord in the male. The aponeurosis is now sutured with a continuous suture of kangaroo tendon, about the size of a number one catgut. The skin is closed without drainage, and the wound dressed with iodoform gauze and moist bichloride gauze 1 : 5,000.

Fracture of the Spine.—W. Lathrop thus summarizes indications for operative intervention: (1) In partial lesions we should operate. (2) Where the lumbar region is involved with lesions of the cauda equina, operation offers the best chance for recovery. (3) In fracture of the spinous process, lamina, or entire neural arch, operation is demanded. (4) Should immediate operation not be done, and we wait six to eight weeks, with the result that paralysis of the bladder and bowel continues, with cystitis and severe bedsores present, we may be sure that nature cannot relieve the case, and an operation is not only indicated but demanded.

American Journal of the Medical Sciences, Dec., 1900.

The Cortical Localization of Sight and Hearing.—Clarence A. Good reports the case of a woman fifty-five years old. About seventeen years previous to her admission to the asylum she had fits at night. These lasted for about two years. When admitted to the hospital she was practically blind. The pupils were equal, reacting to light. She was deaf. The sense of smell was keen. The speech was drawling and the gait lame. She was slightly paretic in all limbs. Cutaneous sensibility was normal so far as could be determined. Mental action was slow and incoherent, memory *nil*. From April, 1892, to her death in November, 1893, she suffered from convulsions. The brain was carefully examined, and the writer draws the following conclusions: 1. Destruction of the cortical visual areas will lead to a degeneration of the cells in the geniculate ganglia and the corpora quadrigemina, and to a degeneration of the nerve fibres of the optic tracts and nerves. 2. The macula lutea of one eye is in connection with the opposite angular gyrus.

The Operative Treatment of Cirrhosis of the Liver.—Charles H. Frazier believes that operative interference has a future in properly selected cases, viz., (1) cases in which the liver is cirrhotic; (2) cases in which there is reason to believe the liver cells are not devoid of function; (3) cases in which internal medication (particularly iodide of potassium) and paracentesis fail to afford relief, or, in other words, in utterly hopeless cases; and (4) cases in which there is no reasonable contraindication. The cases are so hopeless, the technique is so simple, the dangers are so trivial, and the outlook is so promising that the prospects of this mode of treatment becoming an established one seem bright. That surgeons now have at their command a method both rational and reliable of affording relief (sometimes temporary but often permanent) to intractable cases of ascites, seems a very fair conclusion to draw from the accumulated evidence.

The Leucocyte Count in Serous Pleurisy.—John Lovett Morse presents the following conclusions: Serous pleurisy is only exceptionally accompanied by an increase in the number of white corpuscles, and then intermittently. The white count is of value in two ways in the diagnosis of serous pleurisy: If the physical signs are doubtful and there is no leucocytosis the condition is almost certainly not pneumonia or empyema, but serous pleurisy. If there is a serous pleurisy with a continuous leucocytosis, some complication is present. The white count in serous pleurisy affords no information as to the duration of the process, the amount of the fluid, and its increase or diminution. The number of white cells is not influenced by the presence of blood or microscopical pus in the fluid or by the degree of fever.

On the So-Called "Irritable Bladder" in the Female.—Frederic Bierhoff concludes that: 1. The term "vesical hyperæsthesia" or "irritable bladder" is in almost every case in the female erroneously applied. 2. As a true neurosis vesical hyperæsthesia rarely occurs. 3. When vesical hyperæsthesia exists it does so only as a symptom; in the majority of cases as a direct result of some change in the vesical mucous membrane, in the minority as an indirect result of changes in other organs adjoining or near the bladder. 4. The diagnosis of the causative factor must rest upon a thorough examination not only of the bladder, but of the urethra and genital and pelvic organs as well. 5. The treatment must be directed against both the local changes and the causative factors.

A Case of Malaria Presenting the Symptoms of Disseminated Sclerosis, with Necropsy.—By William G. Spiller.

Report of a Case of Extensive Dissecting Aneurism of the Aorta.—By Herbert Swift Carter.

The Laryngoscope, October and November, 1900.

Report of a Case of Spontaneous Cure of a Severe Mastoiditis.—H. S. McGavren saw a girl of ten years with a suppuration from the right middle ear. On examining the left ear he found a depression of the mastoid eminence similar to that following an ordinary operation for mastoiditis except that it was cup-shaped, nearly round, and appeared to be very deep. There was no tenderness. The mother stated that two years before there had been trouble in the left ear, and that finally there had been an exfoliation of a bony mass, about the size of the thumb-nail, and that thereafter all trouble ceased in that ear. No physician was consulted at the time and only household remedies were used.

Adenoids from the Standpoint of Hemorrhage.—I. E. Kimball advises keeping the patient in bed for from twenty-four to forty-eight hours, during which time nothing but cold food should be given. He insists upon the following points: 1. Thoroughness of removal and carefulness in technique at the expense of time. 2. The selection of instruments the best suited to perform the operation safely and efficiently. 3. The positive exclusion of the hemorrhagic diathesis. 4. Competent supervision of the patient until the danger from hemorrhage is over.

Nasal Synechia.—M. D. Lederman advises the use of surgical sponge or spunk for the relief of this condition. One should select the soft elastic variety, which can be cut into any shape, may be covered with any antiseptic powder and allowed to remain in the naris for forty-eight hours. It comes away from the wound very easily and does not cause any bleeding. In introducing the plug we must be careful to avoid bruising the tissues with the end of the forceps, as synechiæ sometimes form behind the site of the tampon.

Primary Epithelioma of the Antrum of Highmore.—H. Holbrook Curtis reports a case of this nature occurring in a woman of fifty years. The points of interest were that the antrum was primarily invaded, that the growth was of an epitheliomatous nature, and that after operative procedure it extended with startling rapidity, finally proving fatal six weeks after the evulsion of the antrum contents. A review of the literature of similar cases closes the report.

Journal of Laryngology, November, 1900.

Anosmia.—A. Onodi divides anosmias into three classes: 1. Essential or true anosmia, either central or peripheral, caused by inflammation of the olfactory region, syphilitic changes, ozena, various central changes, intoxications from various drugs, irritating gases, toxins of various diseases, congenital structural defects, and pigmentary atrophy; 2. Respiratory or mechanical anosmia, caused by any local change preventing free respiration through the nares; and 3. Functional anosmia due generally to hysteria, but which may come from various reflexes, *e.g.*, after ovariotomy, during menstruation, after cauterization of the inferior turbinals, and after extirpation of the Gasserian ganglion. Hallucinations of smell, various parosmias, and kakosmias are frequent precursors of anosmia.

Experiments on Anæsthesia of the Semicircular Canals of the Ear.—G. Gaglio insists on the conclusion that the nystagmatic movements of the eyeballs which are observed to follow destruction of the labyrinth are phenomena not of excitation but of paralysis; that is, of a loss of function of an organ which normally by a reflex path influences the function of the muscles of the eyes. In other words, he admits that the semicircular canals and other parts of the membranous labyrinth originate normally a wave of excitation, slow and continuous, which carried to the nerve

centres and following them, extends to the nerves and muscles of the eyes.

Treatment of Laryngeal Tuberculosis by Intra-Tracheal Injections.—L. Vacher advises the use of the following: Saturated solution of iodoform in ether 100 parts, guaiacol 9 parts, eucalyptol 2 parts, and menthol 1 part. The amount to be injected should not pass beyond 2 c.c. It is better to begin with a smaller quantity. He found that by its use pain was lessened, eating made easier, and respiration more ample.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

POISON IN BEER; A TRAGIC RESULT—PROFESSOR CALMETTE'S HARBEN LECTURES ON PLAGUE—GENERAL MEDICAL COUNCIL—CHILDHOOD SOCIETY—THE "MEDICAL DIGEST"; DEATH OF ITS AUTHOR—OTHER DEATHS.

London, November 30, 1900.

"A thousand cases of poisoning!" "Arsenic in the beer!" Startling enough headings these for the most sensational papers. But they were nearer the truth than many supposed. Manchester is the centre of an epidemic which has for weeks puzzled the medical men. It is said, indeed, that cases may be traced back for six months. Some were at first supposed to be alcoholic peripheral neuritis, but the numbers increased so much that some other explanation was sought. At the various hospitals and infirmaries great numbers of applicants presented anomalous symptoms of peripheral neuritis, and at length it was recognized that they were all drinkers of beer—mostly cheap beer. Then Dr. Reynolds, of the Union Hospital, announced at the Medical Society that he had found arsenic in the beer, and the fact was published in the newspapers. How the arsenic got into the beer was the next question and one more easily solved. Chemists knew the large quantities of glucose employed by brewers and that sulphuric acid is used in its manufacture. They, therefore, at once went for the glucose, and while some samples in use were pure, others were contaminated with arsenic. The amount of glucose used by different brewers varies largely, and this fact goes to explain the remarkable variations noticed in the intensity of the symptoms produced. The typical symptoms of arsenic poisoning can be traced in groups of cases, though individuals present great divergences. Thus the sensory symptoms are said to have been almost always obvious but of every degree of severity, from a sensation of slight numbness to pain so intense that the patients dreaded to be touched. Cramps, too, of the extremities frequently occurred, and there was often impaired motility—in some cases complete paralysis. The catarrh of the respiratory membrane extending over the eyes, nose, and larynx was marked, but did not seem to implicate the bronchi. The digestive membrane seemed less affected; the silvery tongue was present and anorexia common, but vomiting and diarrhœa were often absent. The skin seemed always to suffer. Pigmentation of every degree; erythematous, papular, and vesicular eruptions, followed by desquamation, were generally complained of. Many patients paid little attention to their rashes, but others found them marked enough to alarm them. Others sought advice for intense itching; others again, for constant colds, hoarseness, or smarting and running of the eyes and nose; others, for the nervous symptoms. Many cases so closely resembled beriberi that physicians familiar with the tropics were inclined so to call the trouble.

Not only Manchester but Liverpool and other northern and midland towns have suffered, and about eight hundred patients have sought relief at the various hospitals. It is estimated that more than sixty deaths during the last six months have really been due to arsenical poisoning through beer drinking, although they have, of course, been registered under different names.

Professor Calmette has been over here and delivered the Harben lectures. In them he discussed the bacteriology, diagnosis, clinical appearances, transmission, prevention, and treatment of plague. All that he said went to show the importance of serum treatment. He said it had been clearly proved that after repeated subcutaneous or venous injections of the bacilli, killed by heat, it is possible to inject, after an interval, into small animals cultures which would be fatal without the previous injections. He described Haffkine's mode of preparing dead cultures, and said if they were injected twice or three times at a week's interval, a more durable immunity could be obtained, extending over three or four months in guinea-pigs or monkeys and six months in rats. Haffkine believed a single inoculation might often suffice to render a man immune during an epidemic. But it has been shown that, during the period of immunization, animals are extremely susceptible to minute doses of plague virus. Therefore, if any one were to be inoculated during the incubating period of a slight attack of plague that attack would be aggravated and most likely prove fatal. Other methods of preparation devised to meet this objection were also described. Professor Calmette's own cultures are from a virus taken at Oporto, which has never passed through any animal and which he keeps on gelose and re-fertilizes every eight or ten days, raising the temperature to 36° C. for twenty-four hours each time. These cultures he then places, still on gelose, in large flat bottles and in forty-eight hours an enormous development has taken place. An emulsion with sterilized water is filtered and the microbes are washed, heated up to 70° C. for an hour, and dried in vacuo. Thus the dead bodies of the dried bacilli are obtained free from any trace of toxin and are kept in sealed tubes until wanted. When required for use they are suspended in sterilized salt solution and may be injected under the skin or into a vein.

Prophylaxis must be based on the knowledge that rats and fleas are the principal agents in propagating plague. The best methods of destroying vermin must therefore be employed. Any town threatened with plague should spare no effort to exterminate vermin. If a suspicious case occurs a confidential note detailing the symptoms and the requisite precautions against contagion should be sent to the several medical men. A supply of serum should be at hand.

The General Medical Council met on Tuesday. The president, Sir William Turner, had more excuse than usual for indulging in an address, but his performance ought to have been much curtailed. The finances of the council are in a parlous state, and its interminable discussions at a guinea a minute ought to be shortened. The presidential address is useless. A brief report of anything done since the previous session should be prefixed to a proper programme. Surely the representatives of universities and colleges could understand the programme and proceed without instruction from the chair as to its meaning. But there is a tendency to keep matters in the hands of the chairman, and, to this end, it is convenient to delay the programme and spring important work on the council without notice. A glaring illustration of this truth was furnished when the report of the public-health committee was brought forward. It contained important statements and suggestions, as well as a set of new draft rules concerning the diploma in public health, but it was produced to members only on the morning of the discussion. Why, it ought to have been circulated weeks before. The subject has been debated again and again for years. There was no reason for this absurd method of burking proposals up to the last minute, and objection to such a course was taken by several councillors. A long discussion ended with no more decisive result than in other cases. So the time of the council was squandered, and time in this case is money.

A communication was read from our consul at Chicago about the bogus diploma mill. The names of parties who had corresponded with those engaged in that fraud were sent, but none of them are "registered practitioners."

There are changes in the council—three new members: one, Professor Windle, representing the new Birmingham University—quite an apt illustration of the strange constitution of the council. Here is a brand new university with no graduates—it can have none in the medical faculty for five years—sending its representative to the medical council. Prof. C. B. Ball succeeds Sir Philip Smyly who has resigned. Professor Young takes the place of the late Dr. Leech. A portrait of the last-named gentleman has been presented to the council by a fellow-worker on the pharmacopœia committee.

It was duly reported that all connection of the Dublin College and Hall for the purpose of a conjoint examination ceased last July.

The new "Society for the Study of Disease in Children," or, as it is already being called, the "Children's Society" and the "Childhood Society," has already more than one hundred members. For the present it is arranged to hold the meetings at various hospitals—a chairman being chosen at each meeting from those present.

Doubtless you know the "Medical Digest," a monument of the patience and perseverance of its author, Richard Neale, M.D. Lond., etc. He died on the 22d, aged seventy-three years. He spent about four hours a day for fifty years on this labor of love. It was a costly work to print, and though several editions appeared at rather a high price, it could not pay. Nevertheless, he continued his self-imposed task for the benefit of his profession—the last appendix appearing last year. People ask, Who will continue the work? Can any one be expected to do so? I fear it must be as with your Billings and his "Index."

And Dr. Neale's "Digest" was after all only his hobby. He had an active medical life, too. He retired about three years ago and went to live at the seaside. It was intended to present him with his portrait as a testimonial of the esteem felt for him personally and the admiration with which his devotion to his great work is regarded. Failing health prevented the accomplishment of this purpose and now the end has come.

Dr. Mortimer Granville died on the 23d, aged sixty-seven years. He was at one time on the staff of *The Lancet*, but eventually devoted himself to practice. He wrote on gout and nervous diseases several little books—his best perhaps being on "The Care and Cure of the Insane," which consisted for the most part of articles he had contributed to *The Lancet*. He devised the "percuteur" for treating nervous disease by rapid vibrations and some other instruments—also, I think, a modification of the sphygmograph.

Among other deaths are three octogenarians: Dr. Cordwent, aged eighty-five years; Dr. Riggall, aged eighty-two years; and Deputy-Surgeon-General George Mackay, M.D., aged eighty-one years.

TREATMENT OF GASTROPTOSIS.

To the Editor of the Medical Record.

Sir: In your issue of to-day I read with great interest the article "Gastroptosis," by Dr. George Roe Lockwood, which gives many important original observations. The author, as it appears, has not seen my publication on the same subject in *The Post-Graduate*, March, 1900; otherwise, I am certain he would have mentioned a method of treatment which I have suggested, namely, the support of the abdomen by a piece of rubber plaster cut to cover the whole abdominal wall, tapering off behind, with two extra pieces for support of the hypogastric, inguinal, and iliac regions.

This bandage was described by Dr. H. W. Lincoln[1] who had assisted me in the out-door clinic of the Post-Graduate Medical School when I first applied this method there. My experience now extends over about one hundred cases of gastroptosis with and without nephroptosis, hepatoptosis, a number of cases in which no diagnosis of gastroptosis could be made but where splashing sound could be easily produced and extended far down. The effect was most gratifying in all instances, and it was most remarkable in the cases of reflex vomiting and reflex cough caused by gastroptosis. The distressing symptoms of the so-called nervous dyspepsia would at once disappear after the application of the bandage. I have expressed myself on former occasions to the effect that we have here the ideal treatment for floating kidney, since it is not the displaced kidney which causes gastric symptoms but the coexisting displacement of the stomach. In one case of floating kidney, after the plaster had been borne for only six weeks, I could observe, for months afterward, that the relief had been permanent, the relaxation of the organs or ligaments suspending the organs, together with the relaxation of the abdominal wall, was not found any more; such was, at least, the case when I saw the patient last, six months after the plaster had been removed. In cases in which the skin is tender the rubber plaster may cause unpleasant irritation; in such instances we may apply first to the skin, for protection, Unna's pink rubber plaster and over this the ordinary rubber plaster.

Perhaps some Parisian or Berlin colleague will now discover this method and have it ascribed to his name, in order that the profession in America may find it worth while to take notice of it.

A. Rose, M.D.

New York.

HOW IS MOTILITY IN THE RED BLOOD CELLS EFFECTED?

To the Editor of the Medical Record.

Sir: A recent number of the *Popular Science Monthly* contained an interesting article, entitled "The Psychology of Red," by Havelock Ellis. The author quotes Finsen as having shown that inflammation of the skin caused by chemical or violet light leads to contraction of the red corpuscles. In the same way heat and moisture at about the body temperature lead to contraction of the cells.

But these investigations, like observations of these cells under varying pathological conditions, may give varying results, and hence investigators on this subject may be a little at variance. Without wishing to discredit the influence of physical factors in leading to contraction of these cells, I think they would not in themselves solve the problem as to how the motility is effected, unless numerous observations under varying conditions were made.

The red blood cell, like other cells in the body, has a function to perform in the economy, and it is this physiological function, I believe, which influences the motion more than the light or heat employed. These latter agents may set the cells in motion, but when once this is effected it will be seen that they possess a self-movement which is not to be confounded with a "Brownian movement." This latter motion is an oscillatory or rotary motion on their own axes, and is purely physical. It is seen in the red cells when the specimen of blood to be examined is not in as thin a layer on the cover glass as it ought to be.

Microscopical examinations alone have convinced me that the motility of this cell can be effected in only three ways, and these are the following:

1. By continuous inherent contractility.
2. By alternate contraction and expansion.
3. By the side-to-side movement of the protoplasmic process, which acts as the propelling force and carries the rest of the cell or cell body with it. The process is not retractile.

In my opinion, it is not the light (or the heat) which controls the motion, but the cells must move in conformity with certain physiological laws.

They may be quickened in movement by the chemical products circulating in the blood in pernicious anæmia, but the erroneous deduction must not be made that it is the chemical substance circulating in the blood which propels the cells, any more than light or heat does. The construction of the red cell differs from that of the white cell which has a different function to perform. The white blood cell is a phagocyte, the red cell carries oxygen to the tissues.

"Physiology is the study of the phenomena of life, and knowledge thereof can only be obtained by direct observation and not by analogy or inference" (Dalton's "Physiology," p. 1). If we take one cell, common-sense reasoning would refute the idea that the cell could move in all three ways at one and the same time. But if we study different cells, as in pernicious anæmia, we can observe the motility to be effected in the three different ways before described and in no other way, and investigators who have studied this subject have at times confounded physical or non-vital movements with self-movement or vital movements.

I believe the movements in the red cells in pernicious anæmia are all self-movements. The cells are simply quickened in their movements. Hence I differ from some writers on this subject. The "Brownian movement" causes the cell by the rotary or oscillatory motion to change its position. But this is always slight; and the cell even slightly changes its shape, but this appearance is nearly always stellate. A close observation of both forms of movements in the red blood cells readily distinguishes the two.

The object of this letter is not to discredit careful work, but to show how investigators can, according to the methods employed, arrive at different results.

W. Moser, M.D.

Brooklyn, N. Y.

[1] "Gastroptosis with Special Reference to a new Mechanical Support," Medical News, September 1, 1900.

THE POVERTY OF TROPICAL COUNTRIES AS A CAUSE OF THE FEEBLENESS OF THE NATIVES.

Cordoba, State of Vera Cruz, Mexico.

All men dream of the marvellous riches of the tropics, of the birds with rainbow plumage, of the extravagant flowers, of the elegant tree ferns, of the banana and palms with waving leaves, and of the cocoa palm which furnishes man with everything necessary for life. Indeed, we pity him who has never seen a tropical landscape, as we pity him who has never seen the sea. Then we think of the enormous treasures the English, Spaniards, and Dutch have harvested from their tropical colonies, and naturally we think that the tropics are the richest regions of the world. All this may be true, yet nevertheless, in another sense, instead of being rich, the tropics are fatally poor. Unable to secure the necessaries of life, the people of tropical countries are like the man in whose hand everything turns to gold, yet who perishes of hunger and thirst.

Of all the breadstuffs necessary for man, the tropics furnish only corn and rice, and these only to a limited extent. They have no wheat, rye, or potatoes. The banana may be, as Humboldt says, one hundred and thirty-three times more productive than wheat and forty-four times more so than potatoes, yet it cannot replace either as food. Nor can white men live for any length of time on rice and corn alone, nor on bananas and palm nuts. Native tropical foods can only hold body and soul together, as they furnish but little vigor, energy, and power. No machine can do good work with poor fuel. A man who has neither bread nor meat, cannot get life and strength and push

from tea, coffee, sugar, vanilla, and all the precious spices. Tropical products are merely commercial luxuries, and if the inhabitants of cold climes did not buy them the people of the tropics would lack the necessaries and comforts of life and would yet choke with their own riches.

If we wish to know the effects of the poor diet of the tropics combined with the effects of the heat, we have only to look at the inhabitants of these countries. As a general rule, they are thin, poorly built, and unfit for intellectual or physical labor. Occasional exceptions will only confirm the rule.

Even the foods which are produced are insufficient in amount, so that the least interference with the annual crops results in famines, as is the case in India to-day. Indeed, India has always been the land of fabulous riches of a few and of famines of the millions. Until recently in the cold countries there were none of fabulous wealth and but few famines.

Everything in hot countries is harmful to man; the ground, the water, and the air, swarming with miasms and vermin, and with torment and danger. Life is as much a torment as a pleasure, for whatever makes life worth living is lacking. They depend for indispensable necessaries upon the temperate zones, to which they furnish only the luxuries.

Some one may mention the art, science, and culture of Hindoostan, Ceylon, Java, and the tropical Americas. These were possible when the Aryans and other conquerors who had come from the colder countries had still preserved their original vigor and energy before they mingled with the former inhabitants and degenerated. Then, we ought not to forget that all these great works were done when the great institution of slavery placed tools in the hands of the conquerors to do work they themselves could not do in the heat. In our day, it is machinery, the great liberator of man, which does the work performed in those remote ages by the hundreds of thousands of miserable slaves.

The temperate zone is the one which breeds everything grand, and of these countries, and not of the tropics, Goethe sang,

"Nach der Wärme ziehen sich Musen,
Nach der Wärme Charitinnen."

Lord Macaulay, in his essay on Warren Hastings, *Edinburgh Review*, October, 1841, p. 174, in discussing the prevalent ideas of the wonderful riches of the Indies, said, "Nobody seemed to be aware of what nevertheless was most undoubtedly the truth, that India was a poorer country than countries which in Europe are reckoned poor, than Ireland, for example, or than Portugal. It was confidently believed by lords of the treasury and members for the city that Bengal would not only defray its own charges, but would afford an increased dividend to the proprietors of India stock and large relief to the English finances. These expectations were disappointed." Are not the people of the United States to be disappointed in the Philippines?

F. Semeleder, M.D.

Reviews and Notices.

A Text-Book upon the Pathogenic Bacteria, for Students of Medicine and Physicians. By Joseph McFarland, M.D., Professor of Pathology in the Medico-Chirurgical College, Philadelphia, etc. With 142 illustrations. Third edition, revised and enlarged. Philadelphia: W. B. Saunders & Co. 1900.

This is the third edition of a work which had already a field of usefulness as a convenient handbook of the natural history of the various forms of bacteria. This edition is considerably enlarged and to some extent remodelled. The accounts of the characteristics of the different bacteria are lucid and concise, and in its new form the volume will undoubtedly increase its popularity and usefulness, especially as a reference text-book.

Practical Manual of Diseases of Women and Uterine Therapeutics, for Students and Practitioners. By H. MacNaughton-Jones, M.D., M.Ch., Master of Obstetrics (Honoris Causa), Royal University of Ireland; Fellow of the Royal Colleges of Surgeons of Ireland and Edinburgh; President of the British Gynæcological Society; Formerly University Professor of Midwifery and Diseases of Women and Children, and Examiner in Midwifery and Diseases of Women and Children, in the Royal University of Ireland. Eighth edition, revised and enlarged, with 640 illustrations and 28 plates. New York: William Wood & Co. 1900.

The eighth edition of the English gynæcologist, H. MacNaughton-Jones, shows an improvement that speaks well for the enormous strides gynæcology has made in the last half-dozen years. In every direction has this work been enlarged and improved, making it rather too bulky and cumbersome a volume to handle with ease. Concise is the general analysis of the author, as respects this new edition, when he states in the preface: "Obsolete views, practices, and appliances have been omitted, and I have endeavored to make it, for both student and practitioner, a condensed compendium of gynæcology, including everything of practical importance which has appeared up to the date of its publication." To give a thorough review consciously and critically is much beyond the space allotted to the reviewer. Of the scientific work shown by the writer we can say nothing but the warmest praise. We accept the instructions given us with good grace, for we feel satisfied that such teaching is safe and worthy of the deepest consideration. A few chapters, then, of greater importance and worth will be more fully gone into; not, remember, for purposes other than the frankest criticism, but solely for calling attention to these particular chapters. In the subject "Ectopic Gestation" we call especial attention to his classification of varieties, his careful study of pathology and etiology. When the treatment is advocated we note great progress, and advice which, while radical, paradoxic as it may appear is ultra-conservative. One sentence makes clear the author's positive position. There is no procrastination, no wavering. "Whenever tubal gestation is discovered, operation for the removal of the fœtus and sac should be undertaken at the earliest possible moment." This is the spirit in the right direction, and experts nearly all the world over look upon ectopic gestation as a malignant condition, to be treated as such, immediately and thoroughly, and by the knife only. We cannot accept the statement made that in cases of abdominal or other forms of vicious pregnancy, operation is best at midterm, and not at term or as near such as possible. Surely the experience of Cragin, of New York, in his recent case, as well as of others, proves that a living child can be delivered and remain alive for some years when elective operation is undertaken at term. The chapter on the Bladder has been very thoroughly gone over, largely quoting from Kelly; and while we do not believe that bladder affections should occupy a place in gynecic surgery, the chapter is so complete that it adds very much to the value of the book. The last chapter, which includes the subject of "Massage," would better have been omitted, since mechanical treatment is to-day hardly looked upon by us as a justifiable, let alone a legitimate aid to the cure of diseases peculiar to women.

A Text-Book of the Diseases of Women. By Henry J. Garrigues, A.M., M.D., Gynæcologist to St. Mark's Hospital in New York City; Gynæcologist to the German Dispensary in the City of New York; Consulting Obstetric Surgeon to the New York Maternity Hospital; Consulting Physician to the New York Mothers' Home and Maternity Hospital; Ex-President of the German Medical Society of the City of New York; Fellow of the American Gynæcological Society; Fellow of the New York Academy of Medicine; Member of the Society for Medical Progress, of the Eastern Medical Society, of the New York County Medical Society, etc. With 367 illustrations. Third edition, thoroughly revised. Philadelphia: W. B. Saunders & Co. 1900.

The gynæcological surgeon will find much to interest him in this very complete work on diseases of women. A third edition is now before us, thoroughly revised in every respect and up to date in many particulars. The distinguished author finds many ways of making his particular specialty a decidedly interesting one, and after a careful perusal and study such as we have given the work, we can earnestly recommend it not only to experts in this field but also to practitioners in general. It is just enough theoretical and just enough practical to stand as an excellent text-book for students of medicine. The arrangement of the topics is particularly to be admired, since one topic follows the other in a fashion that makes both reading and study a sort of continuous performance, connected and jointed as it were. The classification is so perfect that one is led gradually and unconsciously into deeper and deeper subject matter, until the book is read through before one is aware of it. His generalization of the various subdivisions is as complete as—we were going to say, an encyclopedia—we have ever read. For example, under "Examination in General," a topic of great importance, the author covers over forty pages, replete with many practical suggestions; but what appealed to us most was the chapter on "Treatment in General," comprising eighty full pages, which certainly increases our previously profound respect for the author, and stamps him as one who knows his subject not alone from the standpoint of the expert in diseases of women, but from the thorough experience obtained in the school of general medicine. Under operative technique we have clear wording, concise and to

the point, making plain even to the most obtuse mind the delineation of the various steps in the many complicated gynæcological operations. All descriptions of operations are, as far as possible, accompanied by good, well-marked plates, which further assist us in our perusal. Speaking of plates, while we feel that they are well worth printing when they have an object in view, we certainly object to one that is unnecessary and flavors of padding. Such is the plate after Spencer Wells, showing the "facies ovariana," which, so far as we could make out without reading what it was all about, might have represented an old lady with a lace hat on. This we would advise the doctor to omit in his next work. We pardon this minor defect, believing full well that the distinguished author will know that the good more than compensates for the little with which we do not agree.

Die Urogenitalmuskulatur des Dammes, mit besonderer Berücksichtigung des Harnblasenverschlusses. Von Dr. Otto Kalischer, in Berlin. Mit 36 farbigen Abbildungen im Text und 33 Tafeln. Berlin: S. Karger. 1900.

The author considers carefully both the striped and the unstriped muscle of the urogenital regions. He takes up the subject from the standpoint of both sexes, treating it both macroscopically and microscopically. Since the muscles in the very young are so much more sharply defined than in the adult, and consequently the origin and insertion far more easily traced, the author begins his studies on the fœtus and the child. The work is richly supplied with illustrations of serial sections taken from subjects representing both sexes and various ages.

Händereinigigung, Händedesinfektion und Händeschutz. Eine experimentelle und kritische Studie. Von Dr. Carl S. Haegler, Docent für Chirurgie und I. Assistenzarzt der chirurgischen Klinik zu Basel. Mit vier Tafeln. Basel: Benno Schwabe. 1900.

The author has been particularly interested in the subjects of wound infection and wound treatment for the last twelve years, and now, in looking over the ground covered, he treats of the localization of micro-organisms on the hand, of the mechanical cleansing and the cleansing by disinfectants of the hands. He takes up the subject of operating-gloves, and concludes his work with a chapter on prophylaxis.

Medical Diagnosis, with Special Reference to Practical Medicine. A Guide to the Knowledge of Discrimination of Diseases. By J. M. Da Costa, M.D., LL.D., Physician to the Pennsylvania Hospital, etc. Ninth edition. Philadelphia and London: J. B. Lippincott Company. 1900.

In calling attention to the ninth edition of this classic, a book which has been the guide of several generations of medical men, thirty-six years having passed since the first edition saw the light, we are saddened with the thought that this is the last revision of the accomplished author, death having put a seal upon his works. In this edition Dr. Da Costa added much new matter, especially in the sections on fevers and diseases of the blood and of the stomach, and in other parts made changes necessitated by the constant advances being made in the direction of greater diagnostic precision. The plan of clinical classification adopted when the work was composed has been retained, since long experience has demonstrated its utility. The list of illustrations has received several additions made necessary by the new process of skiagraphy. Da Costa's work was a pioneer in this essential branch of medicine, and it remains to-day in the first rank of guides to the diagnosis of disease.

Manual of Pathology: Including Bacteriology, the Technique of Post-Mortems, and Methods of Pathological Research. By W. M. Late Coplin, M.D., Professor of Pathology and Bacteriology, Jefferson Medical College, Philadelphia; Pathologist to Jefferson Medical College Hospital and to the Philadelphia (Blockley) Hospital; Bacteriologist to the Pennsylvania State Board of Health. Third edition, revised and enlarged. Three hundred and thirty illustrations and seven colored plates. Philadelphia: P. Blakiston's Son & Co. 1900.

We are glad to welcome a new edition of this exceedingly practical guide for the worker in the post-mortem room and the pathological laboratory. In this edition the number of pages has been increased by two hundred, and that of illustrations by over thirty, and colored plates have been introduced. The work is divided into three parts, viz., technique, general pathology, and special pathology. The aim of the author was the practical one of providing a manual for the actual worker, and not merely furnishing a work of reference for the student and practitioner; but while he has succeeded in attaining the first-named object he has also written a treatise on pathology which may be studied with profit away from the laboratory and may be kept on the shelf as a valuable work of reference by the practitioner. Its usefulness in this respect is enhanced by a very complete index.

Clinical Studies in Vice and in Insanity. By George R. Wilson, M.D., Medical Superintendent, Mavisbank Asylum. New York: The Macmillan Company. 1899.

Drawn from the records of cases kept by the graphic and chart methods in the Mavisbank Asylum the author has presented the subject in a practical manner, quoting cases freely to illustrate his ideas and points of view from which they are discussed. Under "alcoholic predisposition" types of alcoholists are given and considered from the point of view of the question, "what kind of men and women are predisposed." There is included the report of an exceptional instance of voluntary or conscious mania. The cases make interesting reading.

Canine and Feline Surgery. By Frederick T. S. Hobday, F.R.C.V.S. Edinburgh and London: W. & A. K. Johnston. 1900.

This little text-book gives simple directions with illustrations for the management of cases. Much of the material appeared in serial form in the *Journal of Comparative Pathology and Therapeutics*. The book is built upon the clinical experience of several years in the out-door department of the Royal Veterinary College.

La Peste et son Microbe. Par le Dr. Netter, Professeur agrègè à la faculté de médecine de Paris. Paris: Georges Carré et C. Naud, Editeurs. 1900.

A very timely little work including orrhotherapy and vaccination questions. The microbe of the plague is illustrated in five figures on inserted leaves. There are also maps showing localities affected in recent times and charts to illustrate the difference in course in those vaccinated and those not protected.

Normal Histology. By Edward K. Dunham, Ph.B., M.D. Second edition. New York: Lea Brothers & Co. 1900.

There is hardly a book published in the English language that can compete with the one under discussion. It is well adapted to convey to both student and advanced physician all modern views concerning normal histology. It is amply illustrated and written in a comprehensive style.

Contagious Ophthalmia, Acute and Chronic. By Sydney Stephenson, M.D. London: Baillière, Tindall & Cox. 1900.

This is one of the most practical monographs on this subject, dealing with the bacteriology, diagnosis, and treatment of this disease. A great deal is concentrated herein, and it fully serves its purpose.

The Medical Diseases of Childhood. By Nathan Oppenheim, M.D. New York: The Macmillan Company. 1900.

In this new book we are brought face to face with a new method of instructing in the diagnosis and therapeutics of pediatrics. The author maintains that photomicrographs of pathological sections are of greater didactic value than pictures of instruments and photographs of patients. He does not believe in the efficacy of statistics. Some of the illustrations are very good. The book consists of over six hundred and fifty pages, and is printed with clear type on good paper.

University of Pennsylvania: Contributions. William Pepper Laboratory of Clinical Medicine. Philadelphia. 1900.

Whoever is in search of valuable contributions to modern medicine may well read the various articles in this excellent book. Commencing with an article on "Muscular Dystrophy," we next see an article on "Amyotrophic Lateral Sclerosis"; following this, "Cellular Changes"; following, "Venom Injections." Next follows an article on "Melanotic Sarcoma of the Spinal Cord"; then, "Studies in Leukæmia." "The Pathology of the Erythrocyte," "The Blood Plasma after Saline Injections"; then, "The Influences of Immoderate Water-drinking upon Metabolism and Absorption"; then, "Experimental Appendicitis"; then, "Primary Endothelioma of the Left Superior Pulmonary Vein," the "Estimation of Proteids in Milk"; and lastly, "The Etiology and Treatment of Pertussis." The value of the work is greatly enhanced by the excellent illustrations. There is hardly a more complete contribution published, and we feel that the authors should be congratulated, as their type of good work will serve to illustrate what American physicians can do.

Society Reports.

THE MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

ROBERT F. WEIR, M.D., IN THE CHAIR.

Stated Meeting, Held December 10, 1900.

Spinal Anæsthesia.—The entire evening was devoted to a discussion on this subject.

The Neuro-Physiological Aspect.—DR. J. LEONARD CORNING opened he discussion. In response to a request to tell how he first came to make an experiment on spinal anæsthesia, he said that he knew that cocaine possessed a chemical affinity for the sensory nerves, or, at least, for those parts of their structure essential to conduction. Why, then, should not this same affinity hold good of the sensory conducting paths in the cord? To prove this theory he injected twenty minims of a two-per-cent. solution of the hydrochlorate of cocaine into the space situated between the spinous processes of two of the inferior dorsal vertebræ of a young dog. Five minutes after the injection there were evidences of marked inco-ordination in the posterior extremity. A few minutes later there was marked evidence of weakness in the hind legs, but there were no signs whatever of feebleness in the anterior extremities. He tested the condition of sensibility by means of a powerful faradic battery. When the wire brush was applied to the hind legs, there was no reflex action whatever, but when it was applied to either of the anterior extremities the limb was drawn away violently, and the animal set up the most dismal howls. Traces of inco-ordination were observed two hours after the injection had been made. After the lapse of about four hours the dog seemed to have recovered his usual health. The action of the anæsthetic was practically local; however, if the quantity of anæsthetic fluid injected had been greater, the anterior limbs might also have been affected. Absolute localization of the anæsthetia was scarcely possible, but the local action of the drug was greatly favored, so far as the anterior segment of the cord was concerned, by reason of the lethargy of the circulation at this point. Dr. Corning then applied the principle in the human subject, developing the refinements of technique as time and opportunity allowed. Of late there had been much discussion touching a possible poisonous action, more or less permanent, of the anæsthetic upon the central nervous system. The same question was raised when peripheral anæsthesia was enjoying its first vogue. These fears seemed to be ill founded, for when the peripheral nerves were copiously steeped in the anæsthetic, a considerable quantity of the latter must reach the central nervous system through the general circulation, sufficient to set up permanent trouble if such a thing were probable. The previous hypodermic exhibition of morphine, nitroglycerin, and strychnine served to minimize the symptoms. A minor objection was the rather frequent defecation observed. This might be remedied by inserting a short pear-shaped electrode into the lower rectum and passing a faradic current of sufficient intensity to cause continuous contraction of the sphincter. It was possible to achieve the same results by emptying both the rectum and the bladder shortly before making the injection. Vomiting was more difficult to remedy, but this inconvenience was not peculiar to spinal anæsthesia. Abstinence from food for several hours before the injection was made would tend to minimize the difficulty. In fleshy persons a short incision through the integument, immediately over and down to the apices of the spinous processes at the point of election, would enable one to introduce the point of the finger, and so establish the most positive orientation. The question of rigid asepsis was, of course, of the first importance. Spinal anæsthesia must necessarily remain *sub judice* for a long time. Technically complete as it might appear at first view, modifications in method were sure to come about, and no one could foretell what the future might bring forth.

Spinal Analgesia in General Surgery.—DR. GEORGE R. FOWLER, of Brooklyn, continued the discussion. His experience with spinal anæsthesia embraced eighty-one cases, which he divided into the following classes.

I. Operations involving the peritoneum. These numbered twenty-six. In five the analgesia was incomplete, and in three of these the operation was for inguinal hernia, the patients complaining of pain when the distribution of the ilio-inguinal and the ilio-hypogastric nerves was invaded. In all the cases of abdominal section vigorous peritalsis of short sections of the intestinal canal was noted, the contracted areas resembling hard fibrous cords and presenting sharp borders between the contracted and uncontracted portions, which suggested an imminent intussusception. Complaint was made when the hand, previously dipped in an alcoholic solution of corrosive sublimate, came in contact with the peritoneum. The moderate Trendelenburg position was not complained of, but the patients did express discomfort when an extreme elevated pelvis was maintained for some time.

II. Operations in the pelvic region not involving the peritoneum. These cases numbered thirty-four. In cases of varicocele the patients complained of pain when the cord was handled.

III. Amputations. These cases numbered five. In all of these cases the analgesia was absolute and complete, and the length of time which it lasted was ample for the purposes of the operation.

IV. Operations upon the lower extremities not included in the above. These cases numbered thirteen. In a case of ligaturing of the internal saphenous veins, the patient, in spite of the fact that her eyes were bandaged and her ears stuffed with cotton, heard the doctor call for a second knife after an absolutely painless incision of the skin had been made; thereafter she complained of pain upon the slightest touch. The operation of arthrotomy was upon a distended Charcot's joint in a case of advanced locomotor ataxia; here the analgesia lasted one hour and twenty minutes above the knee, and three hours and forty minutes in the parts below the knee.

V. Unclassified operations. These numbered three. In a case of costal resection the patient complained greatly when the periosteum and intercostal nerves were peeled off the bone. In the case of nephrectomy the patient declared her absolute disbelief in the doctor's statement that he had removed the kidney.

Technique of the operation. The space between the third and fourth spinous processes was usually the most available, but either the space above or below that point might be utilized if more easily identified. A sensation of suddenly passing through a tense membrane and entering a free cavity was sometimes distinctly appreciated by the operator as the needle perforated the intraspinous ligament. The use of a double needle permitted the operator to eliminate the accident of occlusion of the lumen of the instrument. A full minute was used for the injection, thus allowing time for the solution to mingle evenly with the cerebro-spinal fluid.

The solution should be freshly made with sterilized water and boiled one minute before being used. A concentrated solution of a definite quantity was no more likely to produce disagreeable symptoms than the same dose in a diluted solution, and its effects

lasted longer. He believed the Sims position rendered the patient more comfortable and tended to relax the muscles of the back. For short operations he used a quarter of a grain, for longer operations half a grain of cocaine.

Extent of the analgesia. Analgesia was present in the soles of the feet in from one to five minutes and extended to the umbilicus in from five to fifteen minutes. In two of his cases it had reached the vertex. In no case did the analgesia subside in the region below the umbilicus under twenty-seven minutes (one case); in all the rest it lasted more than forty minutes. If from one-fourth to three-eighths of a grain dissolved in ten minims of sterilized water be injected, analgesia to and including the perineum may be depended upon for a forty-five minute operation. Probably the extent of the analgesia, as well as its duration, depended somewhat upon the amount of the cerebro-spinal fluid present. Progressive dilution of the cocaine solution from this point of introduction lessened the effect of the drug upon the nerve structures with which it came in contact until, finally, if the amount of cerebro-spinal fluid be larger, this was practically *nil* at points high up in the canal. The circulation of the cerebro-spinal fluid, comparatively free from cocaine, through the lymph spaces in the nerve structure washed out the cocaine solution carried to these by the cerebro-spinal fluid when the injection was first made, until finally the cocaine was so diluted in the general bulk of cerebro-spinal fluid as to be useless for the purpose of analgesia.

Disagreeable features. In the majority of his cases one or more of the disagreeable features—vertigo, nausea, vomiting, headache, chills, rise of temperature and increased pulse rate, pallor, cold sweat, and involuntary defecation and urination upon the operating-table—were present. He would not admit that all these were due to the drug *per se*, in the face of the fact that they had occurred to an equal extent whether large or small doses were used, as well as in cases in which antipyrin or chlorotone were used. Not only this, but in one case of vertigo, pallor, cold sweat, sighing respiration, increased pulse rate with lessened force, cough, nausea, and vomiting, all these symptoms took place when the puncture was made and a drop or two of cerebro-spinal fluid withdrawn and before any injection whatever had been made. Among the cases reported, vertigo was complained of in but three cases. Nausea occurred in about one-half the cases and actual vomiting in about two-thirds of these. In the majority of instances in which vomiting took place it subsided in less than two minutes. Headache occurred in about two-thirds of the cases, the severity and duration varying greatly. Rise of temperature was noted in all the cases. Increased pulse rate always seemed to the doctor to be an incident of the nervousness of the patient rather than an effect of the injection, for the reason that, in the majority of cases, it had been less when the patients left the operating-table than when they were placed upon it. There had seemed to him to be some relation between the nausea and vomiting and the force of the circulation. When the former had been most pronounced, the heart's action had been the feeblest. In recent cases he had attempted to guard the heart during this, the most trying portion of the séance, by a preliminary injection of gr. $\frac{1}{10}$ of strychnine, and with some success. Involunary defecation took place in less than one-eighth of the cases. The patients were conscious of its occurrence in four out of the five cases. The entire aggregation of symptoms, save the nausea and vomiting, had been decidedly lessened since he began the preliminary injection of a gr. $\frac{1}{10}$ dose of strychnine, administered hypodermically. Inasmuch as the dangers from this method probably related entirely to circulatory failure, he deemed it important that provision should be made against this contingency by the preliminary use of a full dose of strychnine.

His cases were not selected ones. Cardiac, renal, and pulmonary lesions had been disregarded for the sake of giving the method an absolutely fair trial. Many of the cases had heart murmurs and not a few were the subjects of degenerative kidney diseases, and one suffered from the gravest of all pulmonary lesions, gangrene of the lungs, from which death occurred one week later. One case had actual suppression of urine, unknown to the speaker at the time of operation. One case of amputation at the hip joint was in an exceedingly weak and feeble old woman of sixty-eight. One case of tuberculous peritonitis was in a patient far advanced in the disease and greatly emaciated, and in whom an incision from the ensiform cartilage to the symphysis pubis was made. The upper part of the incision was necessary to enable him to reach a gastric ulcer. The case of tuberculous ulceration of the thigh was in an old man of sixty-three. Another case of amputation of the leg was in an old and feeble woman of sixty-nine with arterial sclerosis, gangrene of the foot and ankle, in a condition of septicæmia. He referred to many other of the cases operated upon, and he believed that these cases, unsuitable for general anæsthesia in the judgment of any surgeon, showed, as a rule, less pronounced alarming effects from the spinal cocainization than many of the younger and more vigorous subjects in his lists. He had also tried to obtain analgesic effects from antipyrin alone and in combination; also, from a solution of chlorotone; none proved successful.

Conclusions. In closing he stated that, in spite of the favorable experiences with spinal cocainization, he held to the proposition that the ideal anæsthetic agent was one which, with absolute safety, would render the patient entirely oblivious, not only of the pain of the operation, but of each of the disagreeable features, including knowledge of the surroundings, the fear of fatal results, etc. These, together with the disagreeable incident of vomiting, to say nothing of the disgusting occurrence of involuntary urination and defecation while upon the operating-table, should be eliminated from the conscious environment of the patient whenever possible with safety.

Obstetric and Gynæcological Aspect.—Dr. S. Marx continued the discussion on this topic. His first cases were absolute failures for the reason that he did not feel that it was necessary to get cerebro-spinal fluid. One case he had had gave the classical picture of locomotor ataxia, and he thought then that he never would give it again; but afterward he thought it was an ideal anæsthetic. In the hospital he had used it for experimental purposes only. He thought we were invading a dangerous territory, if infection occurred it was beyond one, and the patient was beyond one's help. Up to the present day he had had one hundred and twenty-five spinal punctures, and he had had two absolute failures. In one the anæsthesia was incomplete. The question of failure after spinal anæsthesia might be relative or absolute; some of the cases seen in the hands of other surgeons were only apparent failures. The psychical pain we could not get rid of; there was something so very uncanny about it all, that the psychical fear was very great. The other day he operated upon an old lady who had chronic emphysema, chronic bronchitis, etc., for the radical cure of a hernia; when the needle was thrust in forcibly she cried out; but when the parts were sewn up carefully and deliberately there was no pain. In all these cases he had never failed to get cerebro-spinal fluid; in one case he had punctured six times before he had succeeded. One young man, whom he

was showing how to do the puncture on the cadaver, introduced the needle, endeavoring to get within the cavity, and it was later shown when the abdomen was opened that the needle had been thrust into the peritoneal cavity. It was a simple matter to perforate large blood-vessels, and the conditions could not be controlled, because the trouble was beyond the point of the needle.

The symptoms produced could not be always attributed to the cocaine. These symptoms were quite regular in their occurrence, and they occurred whether cocaine was injected or not. In one case, instead of cocaine solution, a salt solution was injected, and the same symptoms were produced but no anæsthesia. In one case a woman had a terrific headache for three days, with a temperature of nearly 104°, and yet not one drop of cocaine had been used. In another case in which no cocaine was used the same symptoms appeared due to the shock or disturbance in the equilibrium inside the canal. He never gave this injection without expecting to have chill, vertigo, and nausea following; but these symptoms disappeared as soon as the flow of fluid ceased. He did not think these symptoms could be anticipated by the use of any drugs; he believed that some of them were due to nervous conditions and others to shock, for the reason that if powerful sedatives and bromides were given, they did not counteract all the symptoms; this probably proved that all the symptoms were purely nervous. Certain classical symptoms would always arise, but the doctor did not fear them; if the pulse ran up to 140 or 160 or even further, he knew relief would follow when the patient vomited. He was satisfied that gr. $\frac{1}{6}$ or $\frac{1}{12}$ would do all of the work.

Area of analgesia. He did not think that the analgesia was increased by a larger amount of the drug. He had seen analgesia from the ears down. The increased area was not due either to the amount of the drug or to the position of the patient. He had stood patients nearly on their heads to permit gravity to act, and yet no effect on the area of analgesia was produced.

Eucaine had proven an absolute failure. He was now experimenting with the idea of making the solution isotonic with the cerebro-spinal fluid. We knew that the specific gravity of the latter was from 1,009 to 1,010, and he thought, by injecting a solution of the drug of a similar specific gravity as that of the cerebro-spinal fluid, he might be able to get rid of some of the disagreeable symptoms.

Effect upon labor. The effect upon labor was absolutely *nil*, except that the pains continued without the patient being cognizant of them. These patients did not feel the necessity for bearing down; if the anæsthesia was incomplete bearing down followed, which fact showed a relationship between the two. He believed the method was indicated in a prolonged first stage. In gynæcology he did not think this method would ever supplant general anæsthesia. If one injection failed he waited half an hour and then gave a second injection. As to the ultimate results he knew of no deaths from cocaine poisoning, but he had heard of innumerable reports of failures and death, but none was authenticated. A Parisian operator had reported that out of one hundred punctures there were seventeen failures and five deaths, but the name of this operator was refused. These were the reports that tended to damn the operation. Another case of failure was mentioned by a doctor who asked "if he had heard of that death in Carbondale where the patient died three days after the injection." Cocaine did not kill in three days; it killed in three hours. This was an operation that belonged to the domain of skilled, aseptic surgery.

Contraindications. He considered that there were two absolute contraindications: first, in that class of individuals upon whom cocaine had absolutely no effect: second, in the highly neurotic individuals in whom cocaine had absolutely no value.

Intra-Spinal Cocainization from the Anæsthetist's Standpoint.—Dr. S. Ormond Goldan, since the report of his last series of twenty cases, had eleven more to present, making a total of thirty-one cases. The last eleven did not differ materially from the others. Of the thirty-one, nineteen were in women and twelve in men. The punctures were uniformly successful, and, in all his patients, he never failed to get the cerebro-spinal fluid. The twenty-first case presented no special features except that, after the operation, she did not have the intense headache that she did formerly. The twenty-second case was that of an Italian woman in whom it was necessary to substitute chloroform on account of her being such a highly neurotic individual. The twenty-third case was one of vaginal hysterectomy and no after-symptoms were present. The twenty-fourth case was one of vaginal section. The operation was begun ten minutes after the injection, and there was a decided sensation; toward the end of the operation there was no pain. The twenty-fifth case was one of inguinal herniotomy. The anæsthesia extended as far as the chest, the operation was satisfactorily performed, and no after-effects occurred. The twenty-sixth case was also a herniotomy and operation for hemorrhoids. No after-effects occurred. The twenty-seventh case was for the removal of a tuberculous testicle. The anæsthesia was perfect, but during the tying of the cord the patient complained of pain; after the tying of the cord there was no sensation. The analgesia extended to the lower ribs. There were no after-effects. The twenty-eighth case required two injections. The patient was a large, strong fellow, and the doctor had difficulty in getting the man to bend his back, making it almost impossible to get into the canal. The second injection was tried upon the opposite side, between the fourth and fifth lumbar vertebræ, and there no difficulty was experienced in getting in. The twenty-ninth case had ℥ xx. injected without anæsthesia resulting; this patient was not hysterical, and she had much pain during the operation. The thirtieth case was of a highly neurotic person. After waiting five or ten minutes he got fluid; ℥ xx. were injected with perfect anæsthesia. Just before the needle was withdrawn the patient started up, bending the gold needle at a right angle. The thirty-first case was in a highly neurotic patient, but she was carried through without evidences of pain.

Dr. Virgil P. Gibney said that in orthopedic surgery this method had but a small range. He had experience with but five cases, in four of which there was no difficulty in obtaining the cerebro-spinal fluid. In one case a second puncture was required. In some cases of osteotomy the girls rather laughed at the idea of pain. Nausea and vomiting usually occurred in tapping the spinal canal, and he did not think these symptoms should always be attributed to the cocaine used.

Dr. Egbert H. Grandin said his experience with this method was limited to three cases. One was an exploratory abdominal section. He secured the services of an expert, and he furnished a solution of cocaine from the hospital. He had quite an attendance, and all said that the anæsthetic was a failure. He waited twenty-nine minutes and then had to resort to the use of chloroform. Gr. $\frac{1}{5}$ was injected between the fourth and fifth vertebræ and so far as the anæsthetic effect was concerned it did not prove successful. The cocaine was tested afterward and was found to be good. His second case was in a patient upon whom he operated for a pyosalpinx. Here the same expert was obtained, gr. $\frac{1}{5}$ was injected between the fourth

and fifth vertebræ, fluid was obtained as in the first case, he waited nineteen minutes, and when he started to do a posterior section to evacuate the pus the patient shrieked. Both women were neurotic Italians. The third case was one of strangulated hernia occurring in the practice of Dr. Walsh at St. Vincent's Hospital. The same expert was there, and the same anæsthetic was used. The patient was an apoplectic woman seventy-three years of age, with emphysema and a chronic bronchitis—a typical case for this method, *i.e.*, a case in which there were contraindications for the use of ether or chloroform, although the use of the infiltration method or nitrous-oxide gas might not be considered contraindicated. In this case the fluid was obtained, gr. ½ was injected, there was a wait of fifteen minutes, and then the operation was proceeded with. During the course of the operation, which lasted thirty minutes, the woman complained. The hot water poured on caused her distress. The above cases represented his experience with this method of anæsthesia, and he was rather sceptical as to its value. He questioned if there was any surgeon who cared to deal with anything that was uncertain. In dealing with ether and chloroform and nitrous oxide during the past twenty or twenty-five years he had never known them to fail. What was desired in an anæsthetic was certainty. In regard to ether it was stated that it affected the kidneys; might not cocaine, he asked, affect the cord? Might we not get a septic meningitis? Again, chloroform was said to affect the heart; even so might cocaine. He failed to see why cocaine, if injected into the spinal canal, could not affect the heart as cocaine would if injected under the skin. He wished to go on record in the statement that he did not think this method was justifiable in obstetric practice. He considered labor a physiological act, and he did not deem it right to subject these women to the possibility of pathological conditions from the practice of such a procedure. He had always been able to control a tedious first stage by the use of chloral or morphine. In the third stage he never hesitated to give the women chloroform. He knew of only one death that was due to this anæthetics, and that was because the anæsthetist watched him operate instead of watching the patient. In gynæcology he did not think there was a need for such a method. If work of a minor nature was to be performed he preferred nitrous oxide. He did not wish to be regarded as one who was pouring cold water upon these enthusiasts in any way or as blocking the wheels of progress, but he could not help remembering Dr. Corning's statement that "he trembled for the cord."

Dr. W. S. Bainbridge said that, several months ago, he started to experiment with spinal injection. At that time there had been no cases reported of children under eleven years of age, so he determined to try the method in such patients. While he did not believe for a moment that here we had a substitute for the general anæsthetics now employed, he felt that there might be a limited field of usefulness in certain selected cases, both of children and of adults in which ether and chloroform were considered far from safe. In the next issue of the Medical Record would ap pear a paper on analgesia in children, giving the results of his first seven cases. To date he had had some twelve cases with about twenty punctures. Several times he had had the advantage of testing the potency of eucaine in comparison with cocaine in different operations on the same patient. The results so far showed that the former was less certain, more evanescent, the analgesia less complete, and accompanied with the same sequelæ as the latter. Knowing of the failure attributed by a number of observers to the use of heat in the sterilization of the cocaine, he endeavored to secure the same end in some other way. He used ether without heat and secured a satisfactory injection fluid. He had had some cases without nausea or vomiting. In only two involuntary defecation occurred. It was very interesting to see many of the children go through a severe surgical operation, while their attention was wholly taken up by some plaything. One failure he had to report—a boy of ten years received two injections of one-percent. solution of cocaine, in all ℥ xii. He showed all the physiological symptoms presented in the other cases, except the analgesia. Tests were made of the solution which was used with this patient, and it was found to be inert.

Dr. Frederick Kammerer said he had had forty cases in general surgical practice in which he had employed this method, and he had made it a point to use as small a dose of the cocaine as it was possible to give. He found that the method answered best in operations upon the lower extremities, and that abdominal hernias, operations upon the genito-urinary tract, upon the kidneys and bladder seemed to be specially well adapted to this method. He did not think it was so well suited for intra-abdominal work. The most interesting question pertained to the causes of the symptoms. In some of his cases they had been quite alarming, the pulse going to about 180, and then down to 70. He could not look upon these symptoms as not alarming. The after-effects in his cases had been mild—headaches and slight rise of temperature. He asked why these symptoms did not appear after removal of the fluid in lumbar puncture if they were not due to the cocaine. The difference in pressure had nothing to do with the symptoms, nor did operative shock. He thought we were now face to face with an important method which should be approached in a very serious manner.

Dr. Robert F. Weir said that Tuffier, of Paris, showed this brilliant procedure at the recent meeting of the congress, when a large number of physicians, especially English, surrounded him, watching him taking out a kidney, or removing a uterus, and which was one of the most impressive things witnessed in surgery; it excited admiration. Esmarch's bandage treatment of aneurism, too, was a most brilliant thing, but it died down. There were all sorts of fads and fashions in medicine and surgery, and spinal anæsthesia might be one of them. Tuffier had been asked about his deaths, and stated he had had five, but only one was due to the cocaine. Tuffier was an enthusiast in this department. As Dr. Fowler stated, this was something yet in abeyance: it could not yet be classed as a perfectly safe thing to use, certainly not so safe as ether. Was it suitable for those cases in which it was found that ether and chloroform were not advisable? Tuffier said he did not think so. It was interesting to note that most of the Americans present at Tuffier's operation under spinal cocainization had flushed faces from the excitement, all were interested to the same degree. Several said to each other: "We will try this when we get home." This procedure spread in America more widely than in England or France, while Germany practically ignored it. What was being done was largely experimental. At the Roosevelt Hospital it had been tried in ten cases, in three of which eucaine was used and failure resulted. In seven, there were two or three anxious moments, more so than he had ever had with ether in many, many years. Experience at the New York Hospital since 1847 showed that but one death occurred in three thousand cases, and he could not make the statement too strong that this new procedure did not present itself to him in an encouraging way, yet Dr. Weir had collected the following cases: Matas, 9, severe symptoms occurring in 3; Fowler, 81; Goldan, 31, severe symptoms occurring in 1; Keen, 1 which was

fatal (eucaine was used); Lee, 7; La Place, 2, severe symptoms occurring in 1; Murphy, 25; Severaneau, 70; Tuffier, 125, death occurring in 5; Brewer, 6 (eucaine used in 2 of these); Rodman, 2; Weir, 3, severe symptoms occuring in 1 (eucaine used in 1). This made a total of 362 cases, of which 6 were fatal (4 of these Tuffier claimed were not due to the injection) and 6 had severe symptoms. In other words, 1 in every 30 was in danger. Of the failures, Fowler had 5 out of 81; Goldan, 3 out of 31; Murphy, 1 out of 25 (this makes 9 failures in 126 cases in which cocaine was used). Brewer had 2 out of 6 (in 2 eucaine was used); Weir, 1 out of 3 (in 1 eucaine was used). In the 3 cases in which eucaine was used failure followed. He did not see why one should speak of cocaine, when used in this particular line, as ever safe; it seemed that there was a certain amount of risk in thrusting it into the canal. He did not wish to pose as one opposed to this method of anæsthesia. He looked upon it with circumspection. We must wait; a time limit must be allowed before this method was considered of much value.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON SURGERY.

Stated Meeting, December 10, 1900.

CHARLES N. DOWD, M.D., CHAIRMAN.

Total Ureterectomy.—DR. WILLY MEYER presented a man, thirty-seven years of age, who had suffered from pyelonephrosis on the left side several years ago. A surgeon had performed nephrectomy at that time, and had cut off the ureter as low as possible. Four months later some surgeon had found it necessary to drain the bladder, and had done so by means of a perineal section. Later on another surgeon had opened and drained the bladder through a suprapubic incision. On coming under the speaker's observation, he had complained of pain on the left side and running into the extremity, and had also suffered from frequent micturition. Owing to the existence of a valve in the posterior urethra, such as repeatedly occurred after prolonged perineal drainage, he had found it impossible to examine the interior of the bladder with the cystoscope. Not being able to verify the possible presence of a chronic suppurative pyelonephritis he had collected two specimens of urine, one before and the other after massage of the ureter on the suspected side. There had been such a marked difference in the two specimens, and this had been observed so many times, that he had felt satisfied regarding the diagnosis. The attempt to remove the ureter had proved very difficult, because of the fact that at the previous operation the ureter had been cut off so low down. He had had to dissect through a mass of dense adhesions, and had perforated into the peritoneal cavity, so that he had felt compelled to tampon and leave the wound open. The man had made a good recovery. The speaker said it was most important always to test the patency of the ureter by means of a bougie in every case of nephrotomy.

Pecularities in Appendicitis.—DR. JOHN ROGERS presented three cases. The first was that of a boy who had been admitted to St. Francis' Hospital in October. About one pint of fetid pus had been evacuated at the operation, and for a few days he had done well. Then, after some error in diet, he had suddenly developed pain on the left side, and exploration had revealed a large abscess on that side. About November 5th he had begun to have an afternoon rise of temperature, and with this a secondary agglutinative peritonitis simulating abscess. The second case was that of a boy who had been supposed to be ill with typhoid fever for three or four weeks before admission. On examination there was a tumor in the iliac region, and every appearance of sepsis. There was a history of a violent gastro-enteritis following an error in diet, and associated with tenderness on the left side of the abdomen. A diagnosis of appendicitis had been made on this history, and this had been confirmed by the finding of a gangrenous appendix and a collection of pus. The third case was that of a little child who also had had an appendicitis marked by pain in an atypical position. Within an hour after an indiscretion in diet the boy had developed symptoms of a violent gastro-enteritis. There was much abdominal distention with dulness in the region of the gall bladder. The next day an operation had been done, and had revealed a long, crooked, and gangrenous appendix adherent to the duodenum.

DR. A. A. BERG presented a man who had been admitted to the Mount Sinai Hospital about the middle of September with a typical history of suppurative appendicitis. The next day, immediately after bimanual rectal examination, the man had begun to complain of much more pain, and this had been followed by a rapid pulse and a temperature of 104° F. By evening the pain had become excruciating. The abdomen had been at once opened. There was a diffuse, extensive, fetid peritonitis, which could hardly have been of a few hours' formation. The peritonitis appeared to be as general as was usually seen on the operating-table. The exudate had been sponged out from the pelvis and beneath the liver and spleen, and a collection of about four or five ounces of pus had been evacuated around the appendix. This cavity alone was cleansed with peroxide of hydrogen, and a very small wick drain inserted down to the stump of the appendix. As was usual in such cases, the patient had reacted most admirably after the operation. Two or three weeks later a secondary accumulation under the liver had been found and drained. This abscess was probably owing to the fact that the speaker had neglected to sponge out thoroughly the suprahepatic region.

DR. ROBERT T. MORRIS said that left-sided infection in cases of appendicitis was not very rare. He would explain it on the theory that the infective process on the right side had so stimulated leucocytosis as to protect the person on that side, but the infection extending across to the other side of the pelvis was not so quickly met by leucocytosis.

DR. A. A. BERG said that he had very recently seen a little child with a large appendicular abscess occupying the left iliac fossa. This situation was explained by the pathologist on the theory that the streptococci present had wandered out through the peritoneal coat of the appendix across the cavity into the left iliac fossa.

DR. J. F. ERDMANN also reported a case of large left-sided accumulation with a history of appendicitis, and two others situated in the epigastric region. He remarked that the very fetid character of the pus in Dr. Berg's case seemed to him a favorable omen, particularly as he understood the infection had been one of the colon bacillus. His own experience had been that this form of infection gave a very favorable prognosis.

DR. BERG replied that this had not been his experience. It was not so much a question of the nature of the bacteria present as it was as to the quantity of toxins that had been absorbed prior to the operation.

A Method of Fixation of Loose Kidneys.—DR. ROBERT T. MORRIS presented a paper on this subject. He said that since 1881 surgeons had been busily engaged in perfecting the technique of this operation.

Guyon had suggested the removal of a part of the capsule together with the fatty capsule. Some operators since then had even gone so far as to strip the kidney of its capsule, and stitch the bared organ into the muscle defect. Kidneys anchored by Guyon's method usually remained where they were placed, but they had not been free from pain. Senn adopted a radically different procedure when he removed the fat, scarified the capsule, and passed iodoform gauze around the kidney to support it at the site of the wound until granulations had formed on the fibrous capsule. In this way secondary firm adhesions were secured. Dr. Morris said that in the two cases in which he had tried this method the result had been excellent, but the healing-process had been entirely too slow. For the past two years he had made use of a method which he had seen described in literature, but he had been unable to learn the name of the person who had devised it. A quadrangular portion of the fibrous capsule of the kidney was turned up and drawn through a slit in the psoas or quadratus muscle, and sutured there. No injury was done to the parenchyma of the kidney, as occurred when sutures were passed through this part. The insertion of sutures in the parenchyma of the kidney was followed by the formation of more or less fibrous tissue, and this fibrous substitution led at times to neuralgia. His experience with the method just described had been entirely satisfactory.

Frequency of Movable Kidney.—Regarding the frequency of loose kidney the speaker said this question could not be settled until some standard of measurement was adopted; in any event it was known that movable kidney was very common. One of our very prominent pathologists had told him that he almost never saw loose kidney at the post-mortem table. When death occurred the kidney usually slid back into its normal situation, and was fixed there by rigor mortis.

Symptomatology.—He was inclined to believe that direct pressure of a loose kidney on the common bile duct caused jaundice and other symptoms oftener than most authors would lead us to believe. Sometimes great pressure was exerted upon the duodenum, or upon the superior mesenteric vein. A large proportion of these patients presented chronic congestion of the cæcum and appendix with symptoms referable to the appendix. Among the reflex disturbances were those arising from involvement of Meissner's plexus, as for example membranous colitis. In support of this view a case was reported which had occurred in the person of a physician. The membranous colitis had been severe and obstinate, but had been completely relieved by fixation of the kidney, and the man's general health had been greatly improved. The speaker said that he was accustomed to operate only in those cases of movable kidney which were not readily controlled by a support, or in which the suffering continued. There were very few dangerous features about the operation.

Dr. G. M. Edebohls said the advantage claimed for the operation advocated by Dr. Morris was that no sutures were passed through the parenchyma of the kidney. This would certainly appeal to every surgeon, but it must be remembered that a careful series of experiments had shown that regeneration of kidney tissue promptly followed such an injury as was done by the introduction of sutures. If the sutures were absorbable, no permanent trace of their introduction would be left. He had done over two hundred nephropexies, and had made it a rule to pass the sutures through the parenchyma of the kidney. The chief cause of pain in the region of operation after nephropexy was from division of the ilio-inguinal and ilio-gluteal nerves during the operation. If it were impossible to avoid dividing them at the operation, they should be sutured afterward. He would not like to trust entirely to the capsule of the kidney to hold this organ in place. The capsule was often a thin, frail membrane, and the making of the flap of capsule necessitated leaving a large area of denuded kidney. It was strange that Dr. Morris favored this operation, as he seemed to dread so much the results of leaving such a bare surface. He would say that his own experience had taught him that there was no better or surer way of fixing the kidney than by extensively denuding this organ. Whatever fixation was secured by the method advocated in the paper, he believed, was in proportion to the amount of denudation of the kidney. His rule was to anchor the middle of the kidney to the entire length of the space between the last rib and the crest of the ilium. Forty-day catgut should be the suture material used. The capsule should be split on the convex border, and reflected on either side a distance of two or three inches, and then the sutures should be inserted into the reflected portions as well as into the kidney corresponding to the denuded areas. He had examined most of his cases again and again, some of them six or eight years after operation. With the exception of a few of his earlier cases he knew of none that had become loose again.

Dr. Willy Meyer said that after one had partially stripped off the fibrous capsule, one could not be sure that the capsule would not be stripped off further, thus neutralizing the effect of the operation. He had been making use of Dr. Edebohls' method, and had been entirely satisfied with the results. He had been careful to avoid injuring the nerves in the field of operation, and had found no difficulty in doing this.

Dr. A. A. Berg said that he was under the impression that the experiments cited by Dr. Edebohls in support of the theory of regeneration of kidney tissue had been overthrown by the recent investigation of Max Wolff, who had shown that the regeneration was only apparent and due to a hypertrophy.

Dr. Morris, in closing, said that he had also been careful not to injure the large nerves, but he knew of a number of physicians who had had their patients complain of most persistent pain after nephropexy. Possibly this was to be explained by their lack of care in preserving these large nerves.

A New and Simple Method of Sterilizing Sponges by Boiling.—Dr. C. A. Elsberg gave a demonstration of this method. He said that sterilization of sponges by boiling had hithereto been impracticable because it had rendered the sponges inelastic and unfit for use. Other methods of sterilization had been so tedious and troublesome that gauze pads had largely taken the place of sponges in surgery. Sponge consisted essentially of an albuminoid material called "spongein." It was perfectly precipitated from its solutions by a solution containing two per cent. of tannic acid and one per cent. of caustic potash; hence it should be perfectly possible to sterilize sponges in such a solution without destroying their desirable qualities. On testing this in practice the theory had been found correct. The solution could be used again and again, and after infected sponges had been treated in this way bacteriological investigation showed them to have been rendered absolutely sterile. The method of procedure was briefly as follows: The sponges were freed from calcareous matter by immersion for twenty-four hours in eight per cent. muriatic-acid solution, and then thoroughly washed in water. They were next boiled for fifteen minutes in a solution containing one part of potassium hydrate and two parts of tannic acid to one hundred parts of water. The sponges were then washed and squeezed in sterile water or in carbolic-acid or corrosive-sublimate solution until the potassium hydrate and tannic acid solu-

tion had been removed. They were then preserved in a three- to five-per-cent. solution of carbolic acid.

A Cystoscopic Prostatic Incisor.—This instrument was presented by Dr. Willy Meyer. It was easy to understand, said the speaker, that at the time when Freudenberg of Berlin, with the aid of his improved modernized instruments, revived Bottini's operation, the desire to perform the operation under the guidance of the eyes found expression. A few operators proposed suprapubic incision, with the help of which one was enabled not only to see exactly how the beak of the incisor was placed, but also to guide it so, with the finger in the bladder, that it firmly and properly hugged the body of the gland. This procedure, however, was inadvisable, because of the fact that it would interfere, to a greater or less extent, with the passage of the urine through the newly established gateways in the prostatic gland—so necessary in order to insure a good result. Besides, such an incision would unnecessarily complicate the operation.

Thus the only available instrument for the shedding of light on the otherwise obscure field of operation was the cystosocpe. It was, therefore, entirely correct on the part of Freudenberg to insist upon cystoscopy as a preliminary step to Bottini's operation. The visual examination of the bladder might be done either a few days prior to, or simultaneously with, the operation. If the trouble was not far advanced, and the kidneys were not yet affected, it was immaterial when the inspection of the bladder was done. However, in the case of a markedly enlarged prostate accompanied by pronounced renal symptoms, the additional procedure of performing cystoscopy might sometimes mean a serious complication. If done immediately preceding Bottini's operation it would unnecessarily lengthen the operation, and meant repeated introduction of steel instruments, which a large prostate in an advanced stage of the disease often seriously resented. And if done a few days prior to the operation in this class of cases, symptoms of urethral fever might follow its performance, so severe in character as to render impossible the principal part of the work, viz., Bottini's operation. The speaker stated that in cases complicated with pyelo-nephritis he now generally omitted cystoscopy. In view of these drawbacks incidental to cystoscopy as a preliminary step to Bottini's operation, the news that Freudenberg, with the help of Dr. Bierhoff, had constructed an instrument which permitted of simultaneously performing cystoscopy and Bottini's operation was hailed with a great deal of satisfaction. The device was called the cystoscopic prostatic incisor. As a whole, the instrument was a most ingenious one, and beautifully manufactured, as were all the instruments that came from the Berlin firm which had placed also this one upon the market. The cystoscope, with its lamp firmly attached, passed through the centre of the incisor, the same as we found it arranged in the various instruments belonging to the set of Casper's operating cystoscope. The channel through which it passed could also be used for irrigation of the bladder whenever the injected water should become turbid by hemorrhage, etc. As a matter of course, the handle as well as the screw which moved the knife had to be arranged on a somewhat different plan. The cystoscopic prostatic incisor, however, had a number of drawbacks if compared with Freudenberg's improved Bottini's incisor which really was a most beautiful and reliable instrument. These drawbacks, some of which, by the way, had already been mentioned by the two gentlemen who designed the instrument, were evidently unavoidable, and they were certain to make the new cystoscopic prostatic incisor not the principal instrument for Bottini's operation, but only an adjunct, indicated in but a certain number of cases. The drawbacks were: The size (26, the incisor being only 23 French); the shorter shank and smaller knife; the latter point especially was one which would limit the usefulness of the instrument. Referring to Freudenberg's improved incisor, the speaker explained that if we saw to it, when making the posterior (backward) incision through the prostate gland—which must lower the internal urethral opening to the base of the bladder (interior galvano-caustic prostatotomy)—that the beak of the incisor slid gently over the base of the bladder when pulled forward in order to hug the body of the gland; and if we then, by means of the assistant's finger, or our own, in the rectum, measured the distance of the tip of the beak from the external sphincter ani muscle, we were generally enabled to know that the beak was in its proper place. If, furthermore, on repeating this manœuvre a number of times, the distance of the tip of the beak from the sphincter ani muscle was found to be always exactly the same, we could rest assured that we hooked, not a transverse fold of the bladder, but the prostate itself, and that, therefore, we need have no fear of perforating the bladder when proceeding with the operation. The direction of the lateral incisions, whether they be done at an angle of forty-five, sixty, or ninety degrees, was generally not of great value as far as the final result of the operation was concerned. The speaker, therefore, stated that, so far, he had not felt the necessity of doing the operation under the guidance of the eyes. Nevertheless, cases would occur in which it would be of value and importance to see exactly where the beak was located. This applied especially to such cases as had been operated upon before, but in which the obstruction had not yet been entirely overcome, and to early cases of prostatic enlargement. Unfortunately sufferers from the latter condition, so far, were rarely willing to submit to operation. On account of the nearness of the prism to the beak of the incisor, the latter was seen very much magnified, so that only a very narrow circle of the inner surface of the bladder became visible. It was also to be expected that, in the more advanced cases, the generally occurring slight hemorrhage would eventually prevent a proper view when the lateral incisions were made, although the water within the bladder had been changed. In view of the foregoing, it was evident that, before passing definitely upon the value of the instrument, we should have to gain further experience with it. There could be no doubt, though, that it should be in possession of all who took an interest in and were used to perform Bottini's operation.

A Useful Saw for Bier's Osteoplastic Amputation.—Dr. Willy Meyer also exhibited an instrument which he had devised for this purpose. The two essentials were to have the saw blade under strong tension, and so made that it would cut in all directions. The blade in this instrument was 3 mm. wide, and the frame holding this blade was a metallic semicircle. With such an instrument it was possible readily to cut out a very small circle of bone, and hence it was particularly useful in operating upon the humerus and femur.

Neuro-Serum: Destructive and Protective Serum for the Nervous System.—Eugenio Centanni reports the results of his experimentation with an emulsion of nerve substance taken from a sheep. A dose of one-third c.c., introduced by trephining into a rabbit's skull, proves fatal in forty-eight hours. When introduced intravenously, however, it is perfectly well tolerated, although the dose be twenty or thirty times greater than that which kills when introduced into the brain. Ten or more c.c. will prove fatal.—*La Riforma Medica*, November 7, 1900.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending December 15, 1900:

	Cases.	Deaths.
Tuberculosis	210	161
Typhoid fever	104	28
Scarlet fever	171	6
Measles	111	1
Diphtheria	264	37
Laryngeal diphtheria (croup)	12	8
Cerebro-spinal meningitis	0	5
Varicella	80	0
Smallpox	15	0

A Doll House for a Hospital.—One of the most famous of very modern doll houses is the one given to the children of Edinburgh hospital by the King of Siam. In all his travels, so said the soft-spoken, gentle-faced Oriental, nothing else moved him and appealed to him as did that pathetic crowd of white-faced, suffering children: so he went back to London and took counsel with English friends. As a result of this consultation a $500 doll house went to the Children's Hospital at Edinburgh, with the compliments of the King of Siam—and Queen Victoria is second in the hearts of one group of her subjects.—*Sun.*

Comparative Physique of Recruits for the Navy, East and West.—Passed Assistant Surgeon Dr. Edward R. Stitt, United States steamer *Hartford*, in his report to the surgeon-general, United States navy, says: "In connection with the physical examination of the landsmen received from the *Richmond* and *Vermont* on the arrival of the *Hartford* from the Pacific station, a great superiority has been observed as regards the outward manifestations of a sound physique among those born in the middle West over the natives of the Atlantic coast. There were noted among the recruits from the Eastern cities a large number of cases of persons who would probably develop unfitness for the service by reason of catarrhal conditions of throat and nose, as well as from relaxation of inguinal rings; these conditions being far less frequent among the recruits from the Western States. While the most striking feature differentiating the two classes was as regards general appearance, yet the following averages, obtained from measurements, are in a degree indicative of this superiority: Of 163 men, natives of the Eastern coast cities, the averages were: age, 20.3 years; weight, 129 pounds; height, 66 inches; chest expansion, 3.2 inches; circumference of arm, 11 inches, and circumference of thigh, 19 inches. Among those born in the middle West, numbering 92, the average was 20.5 years; average weight, 135 pounds; average height, 67 inches; average chest expansion, 3.4 inches; average circumference of arm, 11.5 inches, and average circumference of thigh, 19.5. Of the 251 recruits who were enlisted for this ship about one year ago, all coming from the West, the following averages pertained at time of first examination: Age, 21; weight, 139 pounds; height, 66.6 inches; chest expansion, 3.2 inches; circumference of arm, 11.7 inches; of thigh, 19 inches."

First Woman Medical Graduate in Germany.—It was in the year 1754, says the Berlin correspondent of the London *Lancet*, that the degree of M.D. was first conferred on a woman in Germany. The *Vossische Zeitung* of July 18, 1754, mentions that the medical faculty of the University of Halle had granted the degree of M.D. to Mrs. Dorothea Christiana Erxlebin, after she had passed the examination with distinction. The title of her dissertation which, according to the custom of that time, was written in Latin, was "Quod nimis cito et jucunde curare sæpe fiat causa nimis tutæ curationis." This lady had been an apprentice of her father, a well-known medical practitioner at Quedlinburg, and as she could not matriculate at a university she learned medicine by reading only. By a royal decree of Frederick the Great, she was then recommended to the faculty of Halle as a candidate for graduation, but she presented herself only after the death of her husband. She also published an essay on the utility of learning for the female sex.

The First Public Free Bath in the United States.—Chicago claims that the Carter Harrison Bath in Maher Street was the first free public bath in the United States, and, so far as is known, the first in the world to be absolutely free; all other public baths prior to the opening of this charging a small fee, ranging from five kreutzers (about two cents) at the Volksbad in Vienna to five cents in the public rain baths in New York City. The Harrison bath was opened to the public in January, 1894, having cost to construct $7,825 for the building and $2,511 for plumbing and heating apparatus. It is needless to say that the Harrison bath has been a conspicuous success.

Knock-Out Drops.—In at least fifty stores in this town, says a writer in the Sunday *Sun*, of December 2d, a stranger can buy chloral hydrate without a physician's prescription. Some of the druggists know what use it is to be put to at the time they sell it, but they charge $2 to $3 for an ounce bottle of the mixture, and so long as they get a good price for it they ask no questions. There are two drug stores in Manhattan that are thriving on the sale of chloral hydrate. Their customers are thieves who make a practice of drugging and robbing men who come to New York to see the town.

Boiling-Point of Water.—Most persons are apt to regard the point at which the water in the domestic saucepan boils as a fixed quantity, unalterable as the laws of the Medes and Persians; but the cooks of a certain town in New Mexico have discovered that in consequence of its great altitude above the sea, water boils there at 202° F. instead of at the normal 212°. This means that all the cooking calculations depending upon the heat of the water have to be revised. Everything from a breakfast egg to a silver side of beef takes longer to cook than it does lower down in the atmosphere. Another thing which militates against the calculations of the ordinary cook of the same town is that the air is so dry that vegetables are deprived of half their natural moisture, and must be left a long time in water to recover themselves before being cooked. In connection with this matter of the boiling-point we might observe that if our cooks at home could only realize the fact that it is impossible to heat the water in an open vessel above boiling-point they would save much of the gas used in so many houses for fuel.—*Chambers' Journal.*

A Remarkable Weapon.—At a meeting of the Zurich Medical Society on October 27th, Professor Krönlein demonstrated a pistol which is creating quite a stir in army circles. A man shot himself with this weapon, a "Selbstlade-Pistole" (self-loading pistol) Patrick Mauser modification. Bergmann was admitted to the surgical clinic with a perforated skull and died soon after. The necropsy revealed a most extraordinary power of destruction in the bullet, there being quite a network of fissures in the skull, besides the

small wounds of entrance and exit. Professor von Bruns, of Tübingen, made experiments on the dead subject with the original Mauser pistol three years ago, and the German army authorities intend to introduce this destructive weapon into the army. The Swiss army authorities have not yet come to a final decision. The weapon is very light and has a light but strong leather case into which the weapon can be so fixed that it serves as a short gun, which greatly facilitates taking aim. The weapon is remarkable from its simplicity of construction and want of screws. The projectile has a diameter of 7.6 mm., and the velocity on firing is 450 metres or 482 yards; the velocity after the bullet has reached a distance of 1,000 metres or 1,093.6 yards is still 120 metres or 130 yards. The simplicity of loading is such that 120 shots can be fired in one minute. It seems a weapon admirably adapted for cavalry forces and mounted infantry.—Zurich correspondent of *The Lancet.*

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended December 14, 1900:

		Cases.	Deaths.
Smallpox—United States.			
California, Oakland	November 24th to December 1st	4	
Georgia, Houston	December 1st to 7th	24	1
Illinois, Chicago	December 1st to 8th	1	
Kansas	December 1st to 8th	9	
Kentucky, Lexington	December 1st to 8th	2	
Russell	November 20th	*	
Michigan, Detroit	December 1st to 8th	2	
Grand Rapids	November 24th to December 1st	1	
Reported present at 28 places	November 25th to December 1st		
Minnesota, Minneapolis	December 1st to 8th	1	
Nebraska, Omaha	November 24th to December 1st	3	
N. Hampshire, Manchester	December 1st to 8th	20	
New York, New York	December 1st to 8th	12	3
Ohio, Ashtabula	December 1st to 8th	4	
Cleveland	December 1st to 8th	32	2
Pennsylvania, Steelton	December 1st to 8th	1	
Tennessee, Memphis	November 24th to December 8th	5

Diabetes Mellitus and its Treatment.—J. H. Reed says that if not more than 25 to 30 gm. of sugar are being passed daily it is not necessary to resort to the severe régime so often forced upon patients. The chief point is to see to it that the patient does not lose flesh. It is a mistake to restrict the diet to the extent to which it is so often done. Antipyrin gr. xv. given morning and night with gr. vi.–viii. of bicarbonate of sodium will show a disappearance from the urine of from 30–50 gm. of sugar within thirty-six hours. Reed prefers, instead of Fowler's solution, the arsenate of sodium in a solution of 3:80 gm. of water, of which a teaspoonful is to be taken at each meal. He also believes that it is not necessary to suppress milk in the dietary because of the lactose it contains, but thinks it should be given, as lactose is not transformed into glucose. In cases of severe diabetes the patient should be allowed to drink freely, to wash out the sugar if possible, instead of allowing it to accumulate. For diabetic coma he advises small doses of antipyrin and rectal injections of bicarbonate of sodium, ʒ ii. in a pint of hot water. He positively interdicts stimulants. He also advises the free use of citrate and carbonate of lithium, regulating the amount according to the quantity of sugar present.—*Physician and Surgeon*, October, 1900.

Pelvic Massage.—E. E. Montgomery describes the process, which he considers advantageous in uterine displacements; in chronic inflammation of the uterus, tubes, and ovaries; in subacute and chronic peritonitis and cellulitis; for the removal of pelvic exudates and unfortunate adhesions after pelvic operations. It is contraindicated in all cases in which it is evident that recent pus collections are present, in suspected ectopic gestation or in recent internal hemorrhage, in ovarian cysts, unless they are very small, when it has been advised that they should be forcibly ruptured with the hope that the cysts will be obliterated and their subsequent growth be prevented. The procedure is absolutely criminal in every case of suspected malignant disease.—*The Therapeutic Gazette*, November 15, 1900.

Books Received.

While the Medical Record *is pleased to receive all new publications which may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

SOME REMARKS ON MEDICINE IN 1800.[1]

BY GEORGE K. WELCH M.D.,

HARTFORD, CONN.

THE subject of the somewhat disconnected paper to which you are about to listen, was suggested by the date assigned for its reading. As this is the last regular meeting but one of our society in the nineteenth century, the topic seemed timely. Not long since the State and county societies celebrated their centennials, and the Hartford Medical Society its semi-centennial, on these occasions many able papers were prepared and read, describing the organization and progress of these societies, containing much interesting information in regard to medicine during their life, and many reminiscences of old physicians, this paper cannot, does not attempt to, and does not desire to compete with these, but it has seemed that by treating of a different portion of the subject some things of interest and perhaps novelty might be set down.

It is a twice-told tale, and would not be interesting or informing to you to discuss at length, with names and dates, the discovery and employment of the stethoscope, the microscope, the clinical thermometer, and vaccination, all of which date, however, in a general way, from the beginning of the century.

Medicine, however, in 1800, with a very accurate knowledge of gross anatomy bequeathed to it from past centuries, waited only for these helps to begin the study of physiology and the symptoms of disease in a scientific way.

A further impulse toward the more scientific study of medicine was the fact that the beginning of the nineteenth century coincides quite closely with the emergence of the art from the domination of the so-called "systems" which, one by one, arose, flourished, and died out. Cullen, who died in 1790, and his pupil Brown, later the author of a rival "system," were almost the last to consider it incumbent upon prominence in their profession to promulgate a complete personal theory of medicine, a "bed of Procrustes," to which all facts, if necessary, must be clipped or stretched to fit.

They, however, had no premonition of this, and their text-books on "Practice" show that each was convinced that his was the only true theory of medicine. In his very long introduction Cullen reviews at length the history of medicine for two centuries, treating first of the Galenists and their partial overthrow by the chemical theory of Paracelsus. He states that later, Galileo's introduction of mathematical reasoning and Lord Bacon's method of induction, with the discovery of the circulation of the blood, favored a disposition to observe facts and make experiments, but (to quote) "it is easy to show that it never could be applied to any great extent in explaining the animal economy."

Stahl's system (which seems to have been an approach to "Christian Science") held that the rational soul governed the whole economy of the body, and was the art of curing by expectation, accompanied by the administration of inert or frivolous remedies, with opposition to the most efficacious.

Hoffman's system followed, laying the cause of all diseases on the nervous system, with spasm and atony as the two extremes. He then refers to the system of Boerhaave, the one under which he was instructed, in which disease was considered due to the laxity or rigidity of the solids and the acidity or alkalinity of the fluids of the body, as the most important of all. Having said this, he goes on to criticise it, root and branch, and points out errors in all its theories, claiming that, although still taught, it should be superseded.

He then discusses Lieutaud's system, which lays stress upon the collection of facts, and while admitting that they are useful, insists that some "system" is necessary for their proper interpretation. He holds up to ridicule, not unjustly perhaps, Lieutaud's remarks on the cure of dropsy: "The cure may be begun by bloodletting in certain conditions, but in others it cannot be employed without danger, it gives relief in difficult breathing, but after it is practised the symptoms are aggravated; . . . some persons have been cured by repeated bloodletting. . . but the remedy. . . has in many instances hastened the fatal result."

Having thus attacked all previous systems, he lays down his own, which, based upon Hoffman's, which he considers the least objectionable, makes diseases dependent upon the motions and moving powers of the animal economy.

Brown, in a shorter but equally combative preface, says that he had wasted twenty precious years of his life (when he was Cullen's disciple) before he discerned the true light. He then details his own division of all diseases into the sthenic and asthenic types, with a copper-plate schedule of diseases and a diagram resembling a thermometer scale divided into eighty degrees with "Mors" at each end, indicating the sthenic and asthenic modes of death. He airily concludes in these words. "Medical art, hitherto conjectural, incoherent and in the great body of it false, is at last reduced to a demonstrated science, which might be called the science of life."

Before this the names of Locke, Sydenham, Boerhaave, and others stand out—men whose natural abilities were so great as to render them successful and famous in spite of imperfect knowledge, prevalent incorrect theories, and lack of instruments of precision. These men, however, were so hampered by their environment that, although they and their predecessors stand credited with single brilliant discoveries, they were not able to advance practical medicine so much as many of less ability since. Many others, whose names have not come down to us, doubtless had much honor in their day, for as Dr. John Brown says, "It is the lot of the successful medical practitioner to be invaluable while alive, and to be forgotten soon after he is dead, and this, not altogether or chiefly from any special ingratitude or injustice on the part of mankind but from the very nature of the case."

Rosari, about this time, was the author of a system by which patients were treated with enormous doses

[1] Read before the Hartford Medical Society, December 3 1900.

of powerful and poisonous drugs, and cases were related at length of persons with slight illness slowly dying, poisoned by aconite, tartar emetic, and digitalis. To this and the unmentionable "system" of "isopathy" homœopathy was to some extent a reaction.

Although the significance of temperature as a symptom of disease had always been recognized, the accurate determination of the body heat as a help to prognosis, and the importance of its fluctuations as a means of diagnosis, was not recognized until the beginning of the nineteenth century. The uniformity of animal heat under extremes of heat and cold was demonstrated in 1775 by Blagden and John Hunter, but the latter held that the temperature of the body was not maintained by the circulation of the blood, but by a different principle, intimately connected with life itself, and considered the seat of the power to be the stomach. In 1787 Cullen published a work on temperature containing much practical matter and it attained considerable notice at the time, but it fell into oblivion, and although the subject of fever and the theories of its production were discussed, there was no endeavor to evolve practical laws until forty years later.

The physician of 1800 had at his service a very complete and accurate knowledge of gross anatomy. Dissection had been practised for five hundred years, and the sixteenth and seventeenth centuries gave birth to many of the great anatomists whose names are forever impressed upon our organs. This being a department of medical science consisting entirely of facts of structure patent to the eye, could not be distorted by the adherent of this or that "system." Small practical use, however, could be made of this anatomical knowledge, in the absence of correct physiology and microscopical anatomy.

Against the statement that the beginning of the nineteenth century marked the fall of all-embracing systems of medicine it might be argued that homœopathy exists at present, and that other absurdities—"Christian Science," osteopathy, and the like—in turn are born, flourish, and die. The difference, however, is, that before 1800 the leaders in the profession felt it necessary, or at least desirable, and a proof of their leadership, that they should originate a special personal theory of disease and its treatment; and that the rank and file of physicians should profess an almost religious adherence to one of these systems; whereas since, the regular profession, finding still, it is true, sufficient opportunities for differences of opinion, is not divided into several hostile camps with opposite opinions on the essential facts of their art, and have placed the mushroom theories of recent times where they belong—in the region of quackery and pretense for the purpose of money-making.

This release of the professional mind from the necessity of constructing or accepting an imaginary theory of medicine, joined to the discovery of means which rendered it no longer necessary to diagnose illness merely by the appearance of the patient and his statements, was a great incentive to the noting and recording of facts which served as a basis for further advance. The achromatic microscope, anæsthesia, and the cell theory toward the middle of the century, and later, antisepsis, powerfully aided this advance, and with steadily increasing rapidity medicine has become what it is to-day.

The illness and death of Washington, occurring so near the close of the last century, caused by an acute disease demanding energetic and intelligent treatment, as well as the great prominence of the patient, naturally attract attention, as the management of his case affords an example of the most approved treatment of that day. From the popular record of his illness in Irving's "Life" it would appear that he died from laryngeal diphtheria after an illness of about one day, and that the principal treatment was large and repeated blood-letting, and external applications, and that the symptoms steadily increased until death. Dr. Craik, the attending physician, perhaps naturally affected and unnerved by the prominence of his patient, seems to have done little. At his second call (to quote) "he pressed his hand in silence, retired from the bedside, and sat by the fire absorbed in grief." Dr. Dick, the consulting physician, was made of sterner stuff, and although he apparently held his peace for eight years, he then wrote a letter to a medical journal in which he speaks very frankly of the treatment pursued by the attending physician, states that the disease was manifestly hastening to a fatal termination, and that he (Dr. Dick) strenuously recommended tracheotomy. He says further (to quote): "At first I had reason to flatter myself that I had obtained the concurrence of the other physicians, and was about to make preparations to carry the measure into immediate execution, when I was rendered unhappy by discovering that Dr. Brown had availed himself of the few minutes of my absence to operate unfavorably on the mind of Dr. Craik, whose assent I was unable to reclaim, by either argument or entreaty. Both of these gentlemen were advanced in years and had each acquired a considerable share of reputation in his profession; but that increased timidity, which is, perhaps, a common attendant on old age, seemed not only to have extinguished all ardor in pursuit of additional celebrity, but also to have created a determination to hazard no part of that stock which had already been acquired. . . . I know not what might have been the result . . . but I shall never cease to regret that the operation was not performed. In this awful and afflicting state of things the lancet was once more resorted to."

This was published about eight years after Washington's death; but Dr. Dick, in 1800, signs with the other physicians an account of Washington's illness published in the *Medical Repository*, in which no mention is made of tracheotomy. It is somewhat long to quote in full, but quite interesting.

"Sometime on Friday, the night of December 13th, General Washington was attacked with an inflammatory affection of the upper part of the windpipe called in technical language cynanche trachealis. The disease commenced with a violent ague accompanied with some pain in the upper and fore part of the throat, a sense of stricture, a cough, and a difficult, rather than a painful, deglutition. The necessity of blood-letting suggested itself to the General, and he procured a bleeder in the neighborhood, who took from his arm in the night twelve or fourteen ounces of blood. He would not by any means be prevailed upon by the family to send for the attending physician until the following morning, who arrived at Mount Vernon about eleven o'clock on Saturday. Discovering the case to be highly alarming, and foreseeing the fatal tendency of the disease, two consulting physicians were immediately sent for. In the interim were employed two copious bleedings, a blister was applied to the part affected, two moderate doses of calomel were given, and an injection was administered, which operated on the lower intestines, but all without any perceptible advantage, the respiration becoming still more difficult and distressing. Upon the arrival of he first of the consulting physicians it was agreed that, as yet there were no signs of accumulation in the bronchial vessels of the lungs to try the result of another bleeding. When about thirty-two ounces of blood were drawn without the smallest apparent alleviation of the disease, vapours of vinegar and water were frequently inhaled, ten grains of calomel were given, succeeded by repeated doses of emetic tartar, amounting in all to five or six grains with no other

effect than a copious discharge from the bowels. The powers of life were now manifestly yielding to the force of the disorder, respiration grew more and more contracted and imperfect, till half past eleven o'clock on Saturday night when retaining the full possession of his intellect he expired without a struggle.

"Several hours before his decease, after repeated efforts to be understood, he succeeded in expressing a desire that he might be permitted to die without interruption. (Signed) James Craik, *Att. Phys.* Elisha C. Dick, *Cons. Phys.*"

The treatment, therefore, of an old man, sick with a disease very exhausting to vitality, and so severe that the illness lasted but twenty-four hours, consisted in the abstraction of between two and three quarts of blood, the administration of about gr. xx. of calomel and gr. vi. of tartar emetic, an injection, with external applications of a blister—and a pressure of the hand. This treatment administered to a well man in so short a time would go far toward preparing him for his last journey.

The repeated regretful statements of the physicians that they noted no benefit from their treatment, with continual repetition of the unsatisfactory means of cure already employed, and their apparent inability to suggest others, and the last request of General Washington that he might be allowed to "die without interruption" have their pathetic side. Brandy was surely in common use at the time, and no doubt "in the house." Peruvian bark, iron, and digitalis were well-known drugs in the materia medica of 1800, but there is no record of their use. The almshouse patient to-day has more rational treatment than the ex-president of the United States had in 1800.

An examination of the medical periodical of one hundred years ago is of greater assistance in showing what the physician of that time was interested in, than a similar examination of the more formal medical treatise. The latter was more under the influence of the moribund theories of medicine. Absurdities are not lacking, but some such will be found by the investigator of 2000 in the periodicals of to-day.

The *Medical Repository* began publication in New York in 1798, and the first four annual volumes will cover the period of our investigation. The magazine was a quarterly containing about 120 pages. The first number begins with a "Circular Address," the gist of which was that the absurd "systems" of medicine, in which facts were made to fit preconceived theories, had lost their value and authority, and that the time had arrived when "Collections of Histories and Observations" and the accurate record of facts should take their place, and was therefore ripe for the establishment of the magazine.

The articles and communications are many of them quite informal, and the publishers print in the second volume a list of their subscribers as a society might print a list of its members. In this list appear the names of two Hartford physicians, Mason F. Coggswell and Nathaniel Dwight. One of the original editors was Elihu H. Smith, who was the first clerk of the Hartford County Medical Society. His death in 1798, at the age of twenty-seven, of yellow fever, then epidemic in New York, is recorded in the second volume, with a very laudatory sketch of his life. In this it is stated that he had practised in Wethersfield, Conn., where (to quote) "finding little employment in the place for any but his social and moral virtues" he went to New York. While there, in addition to his professional and editorial duties he found time to write an opera in three acts entitled "Edwin and Angelina," a copy of which is among the Brinley books in the Watkinson Library in this city, very beautifully printed, in a style which would do credit to typographical art to-day.

There seemed to be a tendency to the publication of papers describing epidemics in comparatively remote countries such as the West Indies, numerous articles on chemistry, of varying degrees of absurdity, as for example a paper by Dr. Gertamer, who had discovered that phosphorus, sulphur, and arsenic were not simple bodies (which, indeed may be true) but composed of carbone, azote, and hydrogene; a paper "proving" that water could be entirely converted into air by repeated freezing, and another on the noxiousness of rain-water and dew. Another long paper treats of "Observations on the Influence of the Moon on Climate and the Animal Economy"; with a proper method of treating diseases when under the power of that luminary. There are also papers of no medical significance whatever, as one describing a cabinet of coins and medals.

It is interesting to note that at this time smallpox inoculation was quite common in the United States, and in one report of such inoculations a physician was proud of the fact that in only one case had he had as many as thirty pustules. In the New York City Dispensary from January to July of this year forty cases of smallpox were treated, all of which ended in recovery. Through the four volumes examined short items and paragraphs occur from time to time in reference to Jenner's experiments in cowpox inoculation, with a gradual increase of confidence in the efficiency of the "vaccine disease" in preventing smallpox, but the subject does not seem to have been regarded with such lively interest as its nature and importance would deserve, and volcanic eruptions in Guadaloupe and a "theory of hail" take up much more space. In a paper on the subject of vaccination it appears that from 1 in 2,000 to 1 in 6,000 died of the vaccine disease.

In the first volume are some matters of local interest. A report of a meeting of the Connecticut Medical Society records the expulsion of Elisha Perkins for patenting his tractors. An open letter from Dr. Coggswell to Dr. E. H. Smith records the diseases prevalent in Hartford and vicinity during the winter, with an account of the weather which appears to have been as changeable as at present. In this account he implies that Indian summer is due about the middle of January. He notes a freshet covering all the town east of Market Street, but states that, in spite of this, catarrhal and pneumonic complaints have been less frequent than usual.

An abstract of a paper on "Sick-Head-ach" read before the Hartford County Society in September, 1797, by Dr. Nathaniel Dwight is printed. His treatment was "half a pint of hard cyder drank on an empty stomach in the morning." We must conclude that if the "head-ach" sees fit to appear after dinner it must wait till the next day for treatment.

Hospital reports are given in each number. In the list of diseases treated the classification is somewhat vague. In one quarter we note seventeen cases of "sore legs" and two of "disordered spine." This quarter was also somewhat exciting, for two patients were "discharged disorderly" and nine "eloped."

A large proportion of the second volume was taken up with papers and discussions upon yellow fever, as was natural in view of the great epidemic then prevailing throughout the United States.

This paragraph also occurs in the same volume: "It is pleasing to find Philadelphia engaged with so much assiduity in the plan of supplying their city with water. Measures are begun and already in forwardness by which the waters of the Schuylkill, which were found upon experiment to be eminently pure and wholesome, will be conveyed to the town in any desirable quantity." One hundred years later the people of the same Philadelphia are engaged with the same assiduity

in avoiding the water of the Schuylkill, which have ceased to be "eminently pure and wholesome."

In Volume III. is a long review of "A History of Epidemic and Pestilential Diseases" written by Noah Webster and published in Hartford in 1800. The book is an endeavor to prove that epidemics of all kinds are closely connected with, and dependent upon, comets, volcanic eruptions, earthquakes, meteors, extremes of temperature, excessive rain and drought, tempests, high winds, plagues of insects and famine: and that all these outbreaks of nature's forces and the resulting epidemics of disease are due to the electric fluid; that when the atmosphere becomes surcharged with electricity the normal action of the animal economy could not be maintained.

The report of a case of chylous dropsy is attractive. I quote: "The patient, a boy of twelve years, was brought to town and tapped. On withdrawing the stilette you may judge our surprise to find a most pure, white and fragrant chyle, or milk, which continued to flow until we had obtained between seven and eight quarts. It was perfectly sweet and pleasant both to the smell and the taste; and after standing through the night afforded a good cream, though not quite so much as is usually obtained from the same quantity of cow's milk." This novel source of dairy products was not, however, destined to long service, for after a second tapping there was no return of the fluid, and recovery took place. The diagnosis was rupture of some of the chyliferous vessels.

In the fourth volume is printed a paper of especial interest to us, entitled "The Improvements, Progress and State of Medicine in the Eighteenth Century; read on the first day of the nineteenth century before the Medical Society of South Carolina." The author, of course, would make the most of his subject and record as much progress as possible. His list of the discoveries and developments of the hundred years then just past is as follows: improvements in anatomy in the preparation of specimens, new operations in surgery, instruction of the deaf, experiments with poison on living animals, establishment of humane societies, cool regimen in fevers and smallpox, establishment of medical societies, hospitals and infirmaries, improvement and simplification of the materia medica, discoveries in chemistry, triumph of physic over smallpox by inoculation and over scurvy by vegetable diet and oxygen, and the abatement of plague and pestilential fevers. This is the record for one hundred years previous to 1800.

The writer of this paper made no prophecy for the coming century, but if he had, we must believe that the facts would have exceeded his reasonable imagination. Can we safely predict an equal advance in the coming twentieth century? At first thought one might say, Why not? The nineteenth century has made discoveries not only wonderful but previously inconceivable in their nature—why should not the twentieth?

Alfred Russel Wallace says that for a proper estimation of the nineteenth century it should be compared, not with the preceding century, but with all historic time; and, doing this, he finds twenty-five discoveries of the first rank in the nineteenth century and fifteen of equal importance in all preceding time. He enumerates these twenty-five, of which five are medical, as follows: railways, steamships, electric telegraph, telephone, matches, gas illumination, electric lighting, photography, the phonograph, Roentgen rays, spectrum analysis, anæsthetics, antiseptic surgery, theory of the conservation of energy, molecular theory of gases, measurement of the velocity of light, rotation of the earth experimentally shown, the uses of dust, definite proportions in chemistry, the meteoric theory, the glacial epoch, the antiquity of man, organic evolution, the cell theory, and the germ theory of disease. The fifteen discoveries of all previous time, of which only one is medical, are the mariner's compass, the steam engine, the telescope, the barometer and thermometer, printing, arabic numerals, alphabetical writing, modern chemistry, gravitation, Kepler's laws, the differential calculus, the circulation of the blood, the finite velocity of light, and the development of geometry.

This enumeration must influence us toward the opinion, that, since the nineteenth century so overshadows not one but all previous centuries, it is not likely that any succeeding one will equal it. The reasonable prophecy seems then to be that the coming century will witness very great advance growing out of discoveries already made, and less discovery of new principles.

Professor Dolbear, in a Boston address, sums it up as follows: "This century inherited the horse, it bequeaths the bicycle, the locomotive, and the automobile; it inherited the goose-quill, it bequeaths the typewriter; it inherited the scythe, it bequeaths the mowing-machine; it inherited the hand printing-press, it bequeaths the Hoe cylinder; it inherited the painted canvas, it bequeaths the photograph; it inherited the hand loom, it bequeaths the cotton and woolen factory; it inherited gunpowder, it bequeaths nitroglycerin; it inherited the tallow dip, it bequeaths the arc and incandescent light; it inherited the galvanic battery, it bequeaths the dynamo, it inherited the flint-lock, it bequeaths the Maxim gun; it inherited the sailing-ship, it bequeaths the steamship; it inherited the beacon signal fire, it bequeaths the telephone and wireless telegraphy; it inherited ordinary light, and it bequeaths the Roentgen ray."

In the field of medicine the antithesis is equally striking. If we note the contrast between the fanciful and changeable theories of medicine in 1800, and the well-grounded and stable theories of to-day; the practically non-existent physiology of 1800, and physiology to-day; the surgery of 1800, without anæsthesia or antisepsis, and surgery to-day; the therapeutics of 1800, with the domination of the lancet, prostrating emetics and cathartics, and modern treatment; the guesswork diagnosis of 1800, and the scientific investigation of the functions of the body with instruments of precision, and of its organs by many well-adaped means, to-day; the wild theories of etiology prevalent in 1800, with the present steadily lengthening list of the diseases the exciting cause of which is certain—we shall be assured that medicine stands abreast of other arts and sciences in the century's advance.

> "For still the new transcends the old,
> In signs and tokens manifold;
> And step by step since time began
> I see the steady gain of man."

The twentieth century enters the hundred-year race with a good pedigree (by "Science" out of "Nature"), vigorous, well-shod, well-trained, and ambitious; sound in wind and limb; "will *not* stand without hitching;" but the race is "against time," and the odds are that the record will not be beaten.

The Treatment of Puerperal Fever. — Victor Steiner reports three such cases. In one of these Marmorek's serum was used with apparently specific results, in another the serum therapy failed, but recovery followed the employment of the more usual measures, and in the third the temperature came down to normal under ordinary treatment before the serum could be obtained. This does not seem to promise very well for the serum therapy, but in desperate cases the author advises its use.—*Centralblatt für Gynäkologie*, November 3, 1900.

A CASE OF GONORRHŒAL ENDOCARDITIS WITH CONGENITAL MALFORMATION OF MITRAL VALVES.[1]

By G. W. McCASKEY, A.M. M.D.,

FORT WAYNE IND.,

PROFESSOR OF CLINICAL MEDICINE AND NERVOUS DISEASES IN THE FORT WAYNE COLLEGE OF MEDICINE; PRESIDENT OF THE INDIANA STATE MEDICAL SOCIETY.

THE following case is reported principally because the physical signs of a cardiac lesion were carefully studied during life and compared with the anatomical changes found at the autopsy, although it presents several other points of considerable interest.

Mr. H——, aged thirty-three years, was first seen in consultation with his attending physician, November 21, 1899. His health was always good until January, 1898, when he had a severe attack of typhoid fever with intestinal hemorrhages, which was very protracted, lasting over three months. Recovery was very slow but was apparently complete and he remained in good health until January, 1899, when his attending physician was called to see him on account of a severe chill following self-catheterization on account of a stricture from an old gonorrhœa. Some five or six weeks later (February, 1899) the present illness began with general malaise, afternoon elevation of temperature ranging from 100° to 102°, with morning temperature 99° or less. From this time there was progressive loss of strength with emaciation. One or two slight pulmonary hemorrhages occurred about the time of my study of the case.

For several weeks preceding my first examination he had been suffering from joint pains in the fingers, toes, and knees. There was also some soreness on deep pressure over the right kidney and a tendency to looseness of the bowels which had been present since the attack of typhoid fever, prior to which there was a tendency to constipation. Urination was normal; there was no headache, nausea, or vomiting. Some dyspnœa was experienced on slight exertion. The tongue was red and irritable, and slightly coated. Physical examination showed the liver greatly enlarged but not indurated. The stomach could be distinctly outlined by succussion and the phonendoscope, and was in the umbilical region, but not much enlarged —principally ptosis. In the left second interspace there were both a diastolic and a systolic bruit, and also a distinct visible impulse synchronous with each systole of the heart. There was marked hypertrophy of the left ventricle, the dulness extending beyond the nipple line, and the impulse was also felt far to the left. The physical examination was otherwise negative.

Uranalysis: Total quantity in twenty-four hours, 1,200 c.c.; sp. gr. 1,019; total solids, 53 gm.; urea, 2.4 per cent., total 29 gm. Trace of albumin by Tanret's and Heller's test but not enough to be estimated by centrifuge. No sugar. Acidity, 40°; uric acid, 1.6 gm.; ratio to urea, 1 to 18; total sulphates, 2.3 gm., ratio 1 ½ to 10; indican, .03 per cent. or 360 mgm. Microscopical: granular casts, pus, and a branched organism closely resembling this form of tubercle bacilli. At another time the albumin was two per cent. by centrifuge estimation.

Blood examination: Red cells 40 per cent. of total bulk by centrifuge method, equivalent to about 4,000,000 per c.mm. Hæmoglobin 65 per cent. White cell count 1,300 to c.mm. A fresh slide showed very poor rouleaux formation, with numerous irregular extracellular granular masses—probably the nuclei and other débris of disintegrated leucocytes.

The diagnosis was endocarditis due either to typhoid or gonorrhœal infection, the lesion being limited to the aortic and mitral valves, and subacute nephritis of recent date and toxic origin. It will be noted that the greatest intensity of the aortic murmur was in the left interspace; but the diagnosis of aortic lesion was nevertheless made on account of the hypertrophy of the left ventricle and associated symptoms. This point will be referred to again later. The bruit was distinctly transmitted posteriorly over the third and fourth ribs near the inner margin of the left scapula. One month after my first visit he had a distinct hemiplegic attack the result of a cardiac embolism, the right side being completely paralyzed. The patient gradually lost strength and flesh and finally died January 4, 1900. Shortly before his death purpuric spots appeared over the upper part of the body and there was marked hæmaturia.

The autopsy was made by attending physicians twenty-four hours after death. The liver was enlarged, weighing five and one-half pounds, and on its outer surface was found a number of calcareous deposits. The gall bladder was greatly distended, the stomach was somewhat dilated and prolapsed. The right lung showed slight general adhesion. Nothing else abnormal was noted. Heart left ventricle greatly hypertrophied, right flabby and thin. The valves on the right side of the heart were perfectly normal in appearance and seemingly competent. The aortic valves were thickened, distorted, roughened and covered with vegetations, and obviously incompetent. The mitral valve was also the seat of inflammatory changes and did not completely close the orifice, although its incompetency was partly due to the predominance of dilatation which greatly enlarged the orifice of the auriculo-ventricular septum. There were two perforations in the posterior cusp of the mitral valve which led into two sac-like formations perhaps half a centimetre in diameter, on its auricular aspect. The spleen was about twice its normal size, and just beneath its capsule were also found calcareous concretions similar to those found on the liver. Both kidneys were enlarged, the right presenting a pelvic hemorrhage.

Scrapings from the aortic valve showed micro-organisms morphologically identical with the gonococcus, which proves the endocarditis to be of gonorrhœal origin. The liver, in sections, showed the typical structure of chronic congestion from heart disease.

There are several points of interest in this case. One of especial interest from a diagnostic viewpoint is the left-sided location of the greatest intensity of a basal murmur, proven by autopsy to have been the result of an aortic lesion. The general statement of the authorities with reference to this question ought to be qualified materially, as there are doubtless many cases in which this anomalous location of the greatest intensity of aortic murmur exists; and unless the exceptional cases are kept well in mind may lead to errors in diagnosis.

With reference to the bruits caused by aortic disease Vierordt[1] says that they are heard over the right second intercostal space; H. A. Hare,[2] that they are heard over the aortic cartilage, Whittaker,[3] that they are heard over the aortic valve or second right interspace; Osler[4] says that the murmur of incompetency is heard over the second right interspace and the stenotic murmur over the aortic cartilage. In his article in Pepper's "System of Medicine," however, vol. iii., p. 663, he says that the systolic murmur may be heard at any point over the base of the heart and usually has its maximum intensity at the sternal end of the right second cartilage or at the sternal junction of the

[4] "Practice of Medicine," p. 640

third rib on the left side; Gibson says[1] that "it may be laid down as a general principle that the maximum intensity of the aortic regurgitant murmur is rarely found in the conventional aortic area." Gibson cites a case with autopsy in which the aortic murmur had the same location as in the case which I have here recorded.

It will thus be seen that it is necessary to take into account all other physical conditions, as well as the location and transmission of bruits, in reaching a conclusion in regard to the precise seat of a cardiac lesion. Another point of interest in connection with the heart is the very marked visible impulse seen in the second left interspace near the sternum. This pulsation is generally regarded as due to a morbid expansion of the conus arteriosus and is therefore present in disease of the right side of the heart. It was a perplexing phenomenon in this case, especially when taken in conjunction with the anomalous location of the greatest intensity of the aortic bruit. I did not have an opportunity of examining the entire heart, but it is positively stated by the physician in the case, who is an intelligent and capable man, that both the right auricle and ventricle were practically normal. The pulsation was probably caused in the manner just indicated; only the over-distention was due to disease, not on the right but upon the left side of the heart, the chain of causes acting through the pulmonary circulation, the evidence of which was furnished by one or two slight hemorrhages, or there may have been a right-sided incompetency due to dilatation, without valvular disease.

Reviewing the case in a general way we find in the first place the evidence of a general infection or autointoxication, for the explanation of which we naturally turn to the typhoid or gonorrhœal disease. The germs of both these diseases may remain in the organism in a latent form for a considerable length of time. The germs of typhoid fever, for instance, have been demonstrated in disease processes within the organism many years after the existence of the acute disease. The protective forces of the organism may be just sufficient to prevent the increase of an organism to a degree of virulence, but not strong enough to bring about its destruction, thus constituting the conditions recently described by Adami under the title of latent infection and subinfection. Such conditions may exist for a long time without manifest symptoms and may finally gain the mastery of the organism, the occurrence of which is heralded by general malaise and joint pains, as in this case, or by various functional and nutritional disturbances. The cause of fever must be sought in the reaction of the organism to the conditions just described, while the nephritis shown by the existence of albumin and casts in the urine may be regarded as the result of the irritant action of the toxins upon these organs in the performance of the function of their elimination. The further disturbances of the chemical processes of the body, which go to make up what is known as nutrition, are further evidenced by the deposition through the blood serum of lime salts beneath the capsules of the liver and spleen.

Temperature as a Sign of Unsuccessful Nursing in the Infant.—During the first four or five days the most important sign of insufficient food is a rise of temperature, "inanition fever," so-called. The range may be from 101° to 102° F., or in extreme cases from 104 to 106° F. If no obvious symptoms of illness are present, such a temperature before the fifth day may be regarded as due to inadequate nursing.—Sajous' "Annual and Analytical Cyclopædia of Practical Medicine," vol. v., p. 219.

THE OPERATIVE TREATMENT OF VARICOSE VEINS OF THE LOWER EXTREMITIES.[1]

By W. C. BORDEN, M.D., F.R.M.S.,

CAPTAIN, MEDICAL DEPARTMENT, U. S. ARMY; PROFESSOR OF SURGICAL PATHOLOGY AND MILITARY SURGERY, GEORGETOWN UNIVERSITY SCHOOL OF MEDICINE, WASHINGTON, D. C.

In order to discuss intelligently the surgical treatment of varicose veins of the lower extremities, certain anatomical peculiarities of the vessels involved and the etiology and pathology of varix have to be considered, as they have a direct bearing upon the treatment of this disease.

Anatomy and Histology of the Saphenous Veins.—In considering the gross and microscopical anatomy of the saphenous veins, it will be necessary to consider only such details as relate particularly to the cause and treatment of the disease under discussion.

The internal saphenous vein in its course upward in the thigh is subcutaneous from its commencement to the saphenous opening, and is supported by the superficial fascia only. The external saphenous is supported by a fold of aponeurosis in the upper part of its course, while the deep veins are surrounded by compressing muscles. This accounts in part for the great susceptibility of the internal saphenous and its branches, and of the distal portion and branches of the external saphenous, to abnormal dilatation; for, the superficial fascia being extremely yielding, and the veins being covered only by it and the elastic skin and subcutaneous tissues, but little support is afforded the blood-vessels. Under the influence of gravitation and blood pressure, the veins contained within the superficial fascia dilate more readily, and can less readily overcome the blood pressure than those veins which run in deep aponeurotic structures and between muscles.

The valves of the veins play an important part in the etiology of varix; and, in this relation, their great variability in number, position, and development is to be noted. In the external saphenous vein, the valves vary in number from seven to twenty. One of these valves is generally situated just at the termination of the vein, and another just at the outer side of the cribriform fascia, but both of these valves are sometimes imperfect or absent. The valves of the external saphenous vary in number from nine to thirteen. In relation to the back blood pressure in the saphenous veins, it is to be noted that the femoral vein above the entrance of the saphenous and the external iliac vein are frequently, and the superior vena cava is constantly, devoid of valves.

Relative to operative procedures, it is important to remember that the saphenous veins are sometimes double and that the double veins are united by anastomotic branches.

It is also important to remember that an anterior branch which ascends the thigh over the position of the femoral artery, and a posterior branch, in the upper and back part of the thigh, which opens in the saphenous a little below the saphenous opening, are liable to enlargement, and that they give off frequent anastomotic branches to the main vein, through which communication may be established with the lower veins of the limb when the main trunk has been ligated. Another very important branch of the saphenous is the nearly constant, communicating vein which extends from the external saphenous near its termination, upward to the internal saphenous. In some cases the external saphenous itself takes the course of this branch and enters into the internal saphenous instead of the popliteal vein; while in other cases it sometimes ascends the back of the thigh to empty into the sciatic vein.

[1] Read before the Medical Society of the District of Columbia, Washington, D. C., October 3, 1900.

These anatomical variations are important to bear in mind when operating; for, if these blood channels exist, it is necessary to ligate or obliterate them, or the collateral circulation set up through them will lead to a recurrence of the disease.

The most important histological peculiarities of the saphenous veins are that the intima is well developed and the media is particularly thick and strong. The media is more developed in the veins of the lower extremities than in any other veins of the body; thus approximating their structure closely to that of the arteries—a structural condition due, probably, to the necessity for overcoming the force of gravity in the blood current in these dependent parts. The media in these veins consists of bundles of muscle cells concentrically arranged and associated with lamellæ of fibro-elastic connective tissue. The muscle cells are quite well developed and, in consequence, these veins have considerable contractile power. This development of the media enables these veins to empty themselves, as they frequently must, working against the force of gravity and without that support and intermittent pressure from surrounding muscles which is given to the deeper veins.

Longitudinal section of a vein shows that the wall of a vein on the cardiac side of the valves is dilated into a pouch or sinus, while on the distal side of the valve the wall is thinner than elsewhere. Under normal conditions the blood pressure and strain are less upon this weaker part of the vein wall, but in abnormal conditions the strain may be so great throughout the entire vein as to bring undue pressure upon the weak wall below the valve—a point of importance in the development of varix.

Etiology of Varix.—The causes of varix may be divided into predisposing and exciting. Of the predisposing causes, weakness of the vein, either congenital or acquired, and the existence of a small number of valves within it, are of major importance.

Soboroff has demonstrated that the veins vary in thickness and strength in different individuals from birth. Under normal conditions of the circulatory system, a perfect balance is maintained between the blood pressure and resistance to pressure by the walls of the blood-vessels. As a result of imperfect development of the vessels, either from hereditary influences (and there is evidence to show that a tendency to weakness of the veins may be transmitted) or their malnutrition, or other factors deleterious to normal tissue development, the vein walls may be weakened, the normal balance between the contained blood and the resisting walls may be disturbed, and, as a result, the veins may yield to the strain from the blood pressure.

When a vein with weak walls has few valves, the tendency to varix is increased; and even when the vein wall is of average strength, if the valves in the vein are few in number, this latter condition alone may act as a predisposing cause. For, with few valves, each segment of the vein between the valves will have to support a longer column of blood than would be the case if the valves were more numerous and nearer together. In consequence, the strain will be greater upon both the valves and the vein wall, and should an exciting cause occur, the vein or valve will be apt to yield to the increased blood pressure. These factors of inequality in vein strength and inequality in number of valves undoubtedly account in part for the asymmetry of varix. Varices, when they occur in both limbs, are rarely symmetrical; and cases are frequently seen in which they exist in one limb only. As statistics show that varix has no predilection for either the right or left lower extremity, the difference in vein strength or in the number of valves must account for the asymmetry of varix, except in those cases in which there is some local exciting cause which is present in one limb only.

Thinness of the vein wall just distal to the valves is, probably, also an important predisposing cause. Under ordinary conditions the strain upon the vein from the internal blood pressure is least just below the valves; but, when the venous flow is obstructed and the vein becomes fully distended with blood, abnormal pressure will be brought to bear upon the vein in this weak place. If such pressure is long continued or frequently repeated, the vein will dilate at this point, and in doing so will pull upon the valves and flatten them out, or separate them. As a result, the valves will become incompetent and the blood column will be extended to the next proximally situated valve, so increasing the height of the blood column, the internal pressure in the vein, and the likelihood to further extension. In this way the entire length of a vein may become varicose, unless the process is stopped by sufficient strength of the vein wall, or removal of the internal pressure by passage of the blood through anastomosing channels. Or, the process may occur in different parts of the same vein or in different veins, thus producing localized varices.

When the process continues until the whole length of a vein is involved, the most pronounced type of varix is produced. It is this process of vein dilatation and valve separation that explains why most varices proceed in a centripetal direction.

Verneuil first described the existence of varices of the deep veins of the lower extremities, and their existence has been noted by other observers, notably by Schwartz and Agnew. Verneuil was so impressed by the occurrence of these deep varices that he formulated: "that far from being rare, deep varices are more common than subcutaneous varices," and "the primitive state of phlebismus is in the deep veins."

While the testimony of numerous observers puts the occasional existence of varices of the deep veins beyond doubt, there is evidence that they do not exist in all cases, and, when they do occur, that they are most commonly associated with the most pronounced types of superficial varix. When the factors causative of varix are excessive, it is reasonable to suppose that varix will be produced in both the superficial and the deep veins. The deep veins, being supported by the deep fascia and subject to intermittent compression by the surrounding muscles, are in a much more favorable position to withstand the effects of the exciting causes of varix than are the superficial veins which have the support of the skin and superficial fascia only. Also, it is known clinically that superficial varices occur with no evidence of implication of the deep veins; and surgical interference often gives complete cure in these cases, which would not be the case if the deep veins were also involved. For these reasons Verneuil's conclusion that superficial varices are always accompanied by deep ones, and that superficial varices always originate in the deep veins, cannot be considered correct for the large majority of cases.

The remaining predisposing causes of varix are sex and age. The factor of age is closely connected with those changes in the walls of the blood-vessels which tend toward increased weakness as age advances. The factor of sex enters in that women are more liable to varix through pressure of the gravid uterus upon the iliac veins.

The exciting causes of varix are physiological or pathological conditions which produce back pressure in the veins by obstructing the venous flow.

Organic diseases of the heart, by causing back pressure in the vena cava and its branches, may be excitive; or back pressure may be produced by pressure upon the great veins in the body by the pregnant uterus; by ovarian or other tumors; by aneurisms of

the aorta; by fecal accumulations in the colon, and so forth; or back pressure may be due to pressure from a tumor in the groin or other part of the limb; or constrictions by artificial appliances. An excellent example of this latter cause is sometimes seen in women who have worn tight garters. In these cases varicosities are frequently very pronounced below the line of constriction by the garter, while above it the veins may be perfectly normal. These cases conclusively prove that varix may be produced by back pressure in the external veins, even when there is no predisposing cause; so disproving the conclusions of Van Lesser, who attempted to produce varicosities in animals by increasing the blood pressure and, failing to do so, assumed that increased blood pressure alone would not cause varix; and, in consequence, concluded that the formation of varix was analogous to the growth of tumors.

Trades and occupations act as exciting causes in persons predisposed to the diseases, particularly those occupations which necessitate the workers remaining long in the erect position, especially in overheated rooms, where tissue relaxation is favored.

Pathological Anatomy. — The first pathological condition in varix is a localized dilatation of the vein. This dilatation may be symmetrical or may be confined to one side of the vein only. Weakness of the vein is generally at first most pronounced in the tunica media, the muscular fibres of which lose their normal tone and contractile power. At the same time, from the continued distention of the vein, the elastic fibres of the connective tissues become stretched, and all three of the coats of the vein lose their contractility. In consequence, the vein remains permanently dilated, and blood stasis occurs. As a result of the blood stasis and the increased blood pressure, leucocytes pass out into the surrounding tissue in abnormal numbers, and transudation of blood serum into the surrounding tissues is increased. Through these pathological processes, the nutrition of the vein is progressively interfered with as these factors become more pronounced.

The passive congestion and the tissue malnutrition produce a condition of chronic inflammation with its accompanying connective-tissue formation. This chronic inflammatory condition affects the intima particularly, so that it frequently becomes greatly thickened, while the media, from destruction of the muscle cells, may become much thinner than normal. The adventitia may be affected in a similar way, and the process may continue so far that the intima may even bulge through the two outer coats, forming purse-like projections on the side of the vein. Even when these changes do not progress so far as this, the conditions of increased blood pressure, destruction of muscle cells in the media, and stretching of all the coats of the vein lead to local dilatations of the vessel wall. From the resulting inequalities of strength, lateral deviations in the course of the vessel are produced, which, with continuation of the trouble, may lead to marked convolutions in the course of the vein. With the dilatation of a vein the valves become incompetent, fall against the walls of the vessels, undergo atrophy, and may even become wholly obliterated.

As a result of the increased exudation of serum in the perivascular connective tissue and lymph spaces, the lymph channels are unable to carry away the excessive exudate and œdema occurs in the neighborhood of the varix. This œdematous condition, by pressure upon the arterial capillaries and venules, may produce such disturbance of nutrition in the surrounding tissues as to cause eczema, ulceration, pseudo-elephantiasis, pigmentation, etc.

From these observations it will be seen that varix may arise either from local insufficiency of a vein, or from excessive blood pressure within a vein, or from a combination of these factors. It will also be seen that varix is at the beginning generally localized and confined to one or several parts of a vein, that it is usually a progressive disease, and that the diseased condition is apt to continue and extend until the whole vein and its branches may be involved. These facts are of importance from a standpoint of treatment, in that, considering the tendency of varix to increase, the necessity for interference in early stages of the trouble becomes evident.

Operative Treatment.—In considering the operative treatment of varix, it is presupposed that it will be attempted only in those cases in which the diseased condition is primarily in the vein and is not due to central causes, such as heart disease, pressure by tumors, or like etiological factors.

Surgical interference in varix was so disastrous in pre-antiseptic days that traditionary timidity still obtains to a large extent, and has been a potent factor in preventing the more general use of radical methods. With the safeguards of modern aseptic methods, this attitude should no longer be maintained. In fact, the milder forms of the disease, in which palliative treatment is ordinarily the only measure thought of, are frequently the very ones in which operative treatment should be adopted. The course of the disease is so generally progressive that this characteristic of the trouble is one of the greatest reasons for early surgical interference. By doing away with the trouble before it has become excessive, extension of the disease may be prevented, as well as the necessity for large operations in the future.

Considering the pathological condition of a varicose vein and the malnutrition of the tissues surrounding it, the conclusion is reached that such a vein is not only physiologically useless but has a continued and increasing ill-effect upon the parts with which it is in relation. Retention of such a blood-vessel under the supposition that it is still functionally useful is an error productive of continued and probably increased trouble to the patient. Experience has demonstrated that the obliteration of one or both of the saphenous veins does not interfere with proper nutrition of the lower limbs—the other superficial and deep veins of the part being sufficient to carry on the circulation. When, therefore, a vessel becomes the seat of varix, that vessel should be removed or obliterated as a blood channel. When this is done, collateral circulation is established by means of the adjoining veins; and, by ridding the part of the diseased blood channel with its greatly increased blood pressure, blood stasis, with its resulting œdema, is done away with. With removal of the œdema, and consequent pressure upon the capillaries, the metabolic cell functions of the part may be normally resumed.

Relative to the surgical means employed to accomplish these results, all modern, approved methods of surgical intervention resolve themselves into two main classes: (*a*) Those procedures which aim to prevent further dilatation, and produce contraction of the vein by occluding it proximally, as in the operation of Remi or Schede; (*b*) those which aim to obliterate the vein by multiple ligation or total removal.

Method by proximal occlusion (single ligation). The first recorded operations by this method were those of Evard Holm, who, in 1799, reported the ligation of the saphenous just below the knee joint in twelve cases. This method was afterward occasionally practised; but, like other operative procedures previous to the discovery of aseptic methods, proved so disastrous from resulting phlebitis and pyæmia that it was seldom done.

After the discovery of aseptic methods, single ligation of the saphenous veins was first brought into

prominence by Trendelenburg, who, in 1890–91, advocated high ligation of the internal saphenous for advanced varix of that vein and its branches. It is interesting to note that a similar operation was advocated by Remi, of Venice, in 1825, and that he, in 1848, published a report of thirty-seven cases treated by high ligation of the internal saphenous with fourteen cures, thirteen cases improved, and but two deaths —a most excellent showing for those days of septic infection.

Remi, in advocating this operation, brought forward the theory that varix of the lower extremity is due to incompetence of the valves of the main saphenous vein; that, in consequence, the vein becomes filled with blood from above downward, distending it and producing the pathological changes and appearances present in this disease. In support of this theory, he showed that elevation of the limb caused the enlarged vein to empty itself, and that with the limb elevated, if the vein was compressed and the limb lowered, the vein would fill from above downward. He also showed that, if the vein was wounded in advanced cases of this touble, the blood flowed in larger quantity from the proximal than from the distal cut end, and adduced this as further evidence of the fact that the vein is filled with blood from above downward. He stated: "We considered ourselves even then (1825) in a condition to prove both by reasoning and facts that the cause of varix in the lower extremity consists in an inverse movement of the blood in the great saphena which gravitates in a column from above to below, from centre to extremity, that hence the valves are powerless and the venous tunicæ are in various ways obliterated." With this theory as a guide, Remi ligated the internal saphenous in the middle of the thigh in order to obliterate the vein at that point and so relieve the distal part of the vein from the pressure of the blood column; holding that, with the removal of this pressure, the dilated vein below the ligature would regain its normal volume and elasticity.

Trendelenburg, in advocating the same operation forty-two years later, brought forward arguments identical with those of Remi without mentioning the publication or work of the latter, apparently not having seen the earlier work of the Venetian surgeon. Trendelenburg's paper is so like Remi's as to appear almost like an amplified translation. There is some slight difference, though both writers are alike in statement of clinical facts and argue alike as to the indications for the operation which they advocate. The difference in the two papers is, that while Remi makes no mention of minor varicosities, referring only to the pronounced variety in which the main trunk of the saphenous is involved, Trendelenburg recognizes but does not discuss the treatment of the smaller varices.

Trendelenburg opens his paper by stating that varicose veins of the leg may be divided into two groups, and says: "There are cases in which the varicose degeneration is restricted to the branches of the vena saphena magna, while the trunk does not show any perceptible change, and again others in which the trunk of the saphena is likewise strongly dilated and varicosely degenerated. Only the last-mentioned group, the cases of simultaneous varicose dilation of the branches and trunk of the saphena, will receive attention." Following this, Trendelenburg confines himself to the cases in which the main saphenous trunk is involved, and advocates high ligation of that vessel for the same reasons that were brought forward by Remi.

With the cardinal indication for high ligation in mind, namely, complete involvement of the main trunk of the saphenous, the operation of high ligation may be resorted to in certain selected cases.

When a varix has extended so far as to involve the entire trunk of the saphenous, the dilatation of the vein and the absence or incompetency of the valves cause the vessel to support a column of blood extending from the lowest dilatation to the heart. In such cases high ligation, by removing the back pressure will in some instances do good, and numerous cures, both of the varix and accompanying ulcers, have been reported as a result of this procedure. In doing this operation, a short length of the vein should be excised between two ligatures; as simple ligation may be eventually followed by re-establishment of the patency of the vessel, while Minkewitsch has shown that no restoration of a vessel can occur after excision of a portion of it.

Unfortunately, relapse occurs in some cases from the free collateral circulation, and, to obviate this, Schede devised a more radical operation, the object of which was to occlude all the subcutaneous veins at the same level. His operation consists in making a circular incision about the leg just below the knee down to the fascia covering the muscles, and ligating the cut ends of all vessels above and below. The superficial nerves are severed, but the internal saphenous nerve may be saved by careful dissection. Cures have been reported, followed, however, in many cases by later breaking down of healed ulcers and persistent local anæsthesia from the severed nerves. In view of the etiology and pathology of varix, it does not seem to the writer that Schede's operation can be considered a proper procedure in any case, as the damage it does to the nerves, and the uncertainty of cure, makes it of doubtful propriety.

The operation of high ligation of the saphenous can well be employed in a certain number of cases, namely, those in which the trunk of the saphenous is dilated throughout, or in those in which the varix is too extensive to remove entire, or in which the condition of the patient is such as to contraindicate an extensive operation. The operation is a simple one, and does not prevent recourse to more extensive operations should they become necessary.

Methods by obliteration of the vein (multiple ligation and excision). Excision. Bearing in mind the fact that a varicose vein is in a pathological condition which makes it a source of continued trouble, it is the opinion of the writer that its entire obliteration or removal is indicated in preference to all other surgical procedures. Fortunately, the great majority of cases are suitable for this treatment. This is particularly the case in those instances in which the varices are localized; namely, in which only a portion of a vein is involved, or in which a vein or its branches are involved, in different parts, the intervening portions being normal.

A small varix will frequently produce great discomfort and almost incapacitate for manual labor through swelling of the limb, pain, soreness, and a feeling of intense fatigue in the part affected. When such cases are treated by excision of the diseased vein, the cure is often complete, particularly if the case is operated upon early—the completeness of the cure conclusively negativing the assertion that superficial varix is always preceded or accompanied by varix of the deep veins. The writer has had a number of such cases, and from them is fully satisfied that removal of the vein should be practised rather than palliative treatment in all localized varices in which the consent of the patient can be secured.

The removal of the more extensive varices by excision is to be recommended in all cases in which the condition of the patient will warrant it. The entire internal saphenous has been repeatedly removed with brilliant result. The writer, in the case of a soldier who was totally incapacitated from military duty on account of a varix involving the entire internal sa-

phenous and several of its branches, excised the vessel from the saphenous opening to a point midway of the leg, and either removed the varicose branches or placed multiple ligations upon them. Recovery was complete, and eight months later the soldier reported that he was doing full duty with no inconvenience.

In this, as in all operations on the veins, measures of strictest asepsis should be employed, and ulcers, if present, be thoroughly cauterized with the Paquelin cautery. Exposure of the vein is facilitated if the limb is depressed and constricted by an elastic bandage placed proximally to the enlarged vein. By beginning at the proximal end of the varicose portion and dissection toward the distal part, ligating the branches as they are reached, the vein is kept distended with blood, and its course and condition can be easily determined. If emptied, it contracts, and it then becomes difficult to determine where the varicose part of the vein ends and the normal begins.

Multiple ligation. Multiple ligation is to be resorted to in those cases in which the varix is so extensive as to render excision of the entire varix impossible, or in which the condition of the patient is such as not to allow the more extensive incision required for excision. In such cases multiple ligation, or multiple ligation combined with excision, is to be advocated.

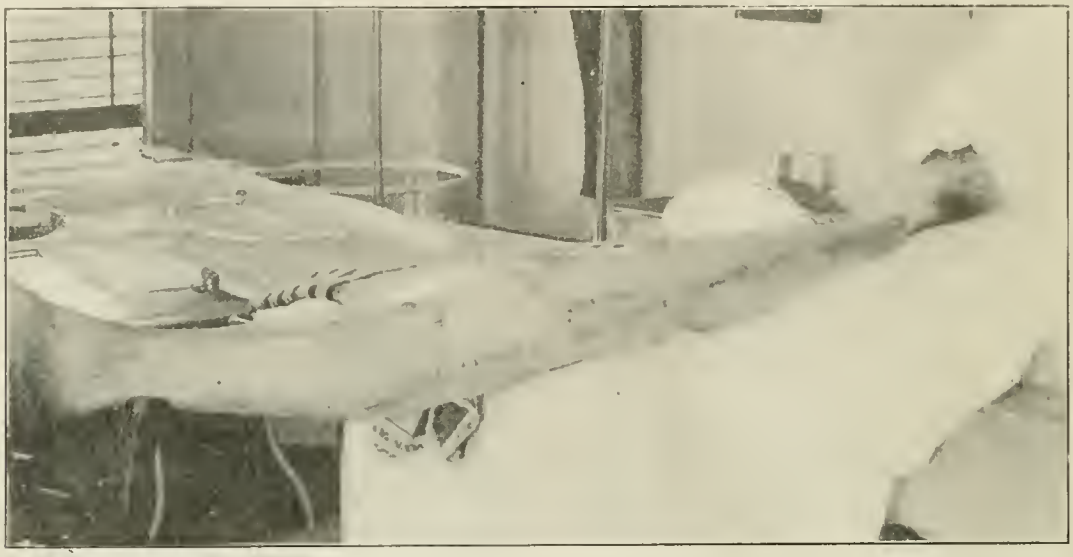
In the operation of multiple ligation it is of cardinal importance to apply the ligatures near together, at most not more than two inches apart. As early as 1772 Hewson demonstrated that blood does not coagulate in a normal blood-vessel, and Brücke and others have shown that the blood will remain fluid in a blood-vessel so long as the intima is not injured by mechanical or pathological processes. When, therefore, a vein is ligated antiseptically, the clot produced by mechanical injury to the intima in no case extends beyond the first anastomotic branch. In consequence, if ligatures are not placed so closely together as to occlude every anastomotic branch, the vein will remain filled with blood and the varix will not be cured.

In pre-antiseptic days the surgeon in operating upon varix was aided by septic infection, for the resulting endophlebitis extended along the vein and caused inflammatory changes in the intima which led to thrombosis and obliterative phlebitis. In aseptic ligation these changes do not occur, and obliteration of the vein can be accomplished only by placing the ligatures so close together as entirely to obliterate the vein as a blood channel.

The operation of multiple ligation is a simple one, only requiring care as to asepsis and in so placing the ligatures as not to include the nerve which accompanies the vessel. The operation is not so grave as complete excision, and is, therefore, indicated in weak individuals; but, if properly done, it is more tedious than excision.

Conclusions.—From the foregoing it will be seen that the writer, arguing from the pathological condition of a varicose vein, favors complete excision in all cases in which no contraindications are present; that, following this, multiple ligation, or excision combined with multiple ligation, is advocated; and, in cases in which these measures are contraindicated and the entire saphenous is dilated, trial of the high ligation of Remi and Trendelenburg.

Also, arguing from the etiology, pathology, and proneness of varix to extend, the writer advocates early operation. The tendency is too much toward palliative treatment in this disease, especially in its early stages. Under palliative treatment, the disease too often extends until serious complications occur, or operations of magnitude are demanded. By removing the diseased vein when the diseased area is small and localized, the varix may be permanently cured. If more early operations were done we would see fewer extreme cases in which the whole or a large part of the saphenous and its branches are involved.



Combined excision and multiple ligation. The photograph shows the condition of the part on the ninth day when the first dressing was removed. The skin was united with interrupted sutures of horsehair. Cure was complete and permanent.

The Curability of Inebriety by Medical Treatment.—T. D. Crothers believes that when inebrity shall be more generally studied and treated as a disease by the profession, a degree of curability will be obtained far beyond any present expectation. The continued or occasional excessive use of spirits to intoxication is not the disease, but is a symptom of some central irritation and exhaustion; also of poisoning and starvation. Many of these cases are self-limited, and follow a certain course, dying away after a time. The subsidence of the drink symptom by the removal of the exciting causes and building up the system to greater vigor and health is the only rational treatment. The highest medical judgment will be needed to determine the exact condition in each case, and the possible range of remedies required—not any one drug or combination of drugs, not so-called moral remedies, not appeals to the will power, but a clear, broad, scientific application of every rational means and measure demanded.—*St. Louis Medical Review*, October 13, 1900.

TWO UNUSUAL CASES OF APHASIA, WITH SPECIAL REFERENCE TO THE SO-CALLED NAMING CENTRE.[1]

By GRAEME M. HAMMOND, LL.B., M.D.,

NEW YORK.

At the meeting of the American Neurological Association in 1899 I reported a case of aphasia which seemed to me, at that time, to be a most valuable contribution to the subject of cerebral localization. It was one in which a small circumscribed lesion in the posterior part of the superior temporal convolution was accompanied by an absolute inability for naming persons and things. In other words, it seemed to indicate the topographical position of the "naming centre."

A naming centre existed only as a proposition advanced by Broadbent[2] until Mills[3] reported a case which seemed to remove the naming centre from its theoretical position to one established upon a firm foundation of fact. In Mills' case, in which absolute anomia was the most prominent feature, a tumor was discovered post mortem in the inferior temporal convolution. Mills therefore concluded, and his conclusion seemed inevitable, that there is a distinct naming centre, and that it is situated in the inferior temporal convolution.

In my case the anomia was as prominent a symptom as in Mills' case, but the lesion, plainly brought to view by a surgical operation, was found to be in the posterior third of the superior temporal convolution, in no wise corresponding topographically to the lesion observed by Mills.

I attempted to harmonize these two cases, which seemed so hopelessly antagonistic from a localization point of view, by the following theory:[4] "The first cells in the higher auditory centre which begin to register the memory of words heard, register the memory of names. The first words the infant learns are names such as 'papa,' 'mamma,' 'bow-wow,' etc. These, with other simple names, for a considerable period of time constitute the child's entire vocabulary.

"Can it be claimed that all of the cells in the higher auditory centre in all infants develop simultaneously and with the same degree of perfection, and that therefore the cells in a particular and preordained part of the auditory word centre are ready and prepared for the reception of name sounds and the memorizing of those words? Is it not more probable, yes even certain, that some cells are in a higher state of development than others, and that the cells which are most highly organized are the ones which will naturally register and retain the memories of names? These cells of superior development may be situated in any part of the higher auditory centre. If this is the case the location of the group of cells in which name memories are stored, while being an integral part of the higher auditory centre, might differ widely in location in different individuals." But in the light of the subsequent study of both Mills' case and my own, and of another one of my own which I will present to you in a moment, it would seem that this theory, while possibly true in the main, is not necessary to explain the condition of anomia in limited lesions of the speech area. In order to make my remarks more comprehensive it will be necessary briefly to refer to the report of this case already published, otherwise the subsequent developments observed would lose their relevancy.

The patient, who is now brought before you for your inspection, is twenty-five years old, of fair education, and a clerk by occupation. He denies syphilis, and there is no evidence of his having had that disease. He admits that he drinks alcoholic liquors, but says he seldom does so to excess. His physician said he had observed albumin and granular casts in the urine for several months previous to his injury. He was apparently in good health at the time he was hurt. During a fight he was knocked down by being struck over the left temporal bone with a loaded whip-handle. He was not rendered unconscious. He did not have any difficulty in conversing for several hours afterward. At the end of that period he was suddenly seized with a general convulsion, which was severe and prolonged. When he regained consciousness it was observed he had completely lost the ability to name objects and persons.

He was brought to the Post-Graduate Hospital a few days later, when I first saw him. I had him under observation for several days, during which time his symptoms were carefully observed both by myself and by my colleague, Dr. Joseph Collins, who rendered me valuable assistance.

There were no disorders of taste, smell, vision, or hearing. There were no motor paralyses, and no disturbance of sensibility. There was no motor aphasia. All the words he could say were pronounced distinctly and fluently. There was no word blindness. All simple directions and orders written out for him were promptly understood and executed. He could talk and voluntarily say almost all words except the names of objects and persons. He readily recognized all objects he saw, and indicated by appropriate gestures that he understood what they were, and what they were used for, but he could not say the name of a single one, even when he was told what the name was. When shown a cup and asked if he knew what it was, he said: "Yes, sir; yes, sir," and raised it to his lips. When told to describe how he was hurt he said: "Yes, sir: I was struck on the—yes, sir; here, sir (pointing to his head), by (after an attempt to remember the person's name) an acquaintance. He hit me with a" (here a pantomime illustrating the size and shape of the implement he was struck with).

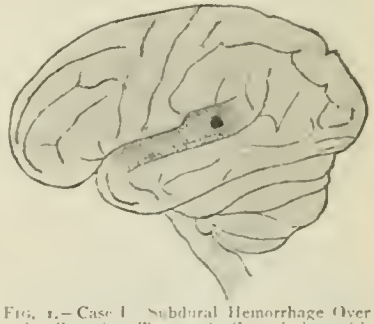


FIG. 1.—Case I. Subdural Hemorrhage Over the Superior Temporal Convolution with Laceration of the Cortex. Deep shading indicates the extent of the hemorrhage; the black spot, the location of the laceration.

He could copy both writing and printing. In voluntary writing and in writing from dictation he made frequent errors. When told to write the alphabet he made many mistakes, and when directed to write "cat" and "horse" he wrote "ceat" and "heort." He recognized that what he had written was wrong, but could not correct it.

He was slightly word deaf. Generally he comprehended all that was said, and almost always recognized enough words in every sentence to enable him to grasp the meaning. But occasionally a sentence had to be repeated, or some of the words changed before he could understand. There was slight choked disc in the right eye. The diagnosis was made of subdural hemorrhage over the posterior portion of the superior temporal gyrus. An operation was performed by Dr. Seneca Powell two weeks after the injury. A linear fracture was found in the left temporal bone, and there was a subdural clot which covered the entire superior temporal gyrus, but did not extend in any direction beyond that convolution. At a point at

[4] Hammond: "A Case of Subdural Hemorrhage, etc." Trans. Amer. Neurol. Assn., 1899.

about the junction of the posterior and middle thirds of this gyrus, there was a rupture of the cortex. This was about a quarter of an inch in diameter, and extended straight into the cerebrum to a depth of about an inch. The lesion was evidently caused by the pressure of blood, as it was certainly two and a half inches posterior to the fracture, and could hardly have been caused by the direct violence of the blow.

His present condition, now nearly a year after his injury, is as follows: In reading aloud he reads simple words and understands them. He says he reads the papers, but often comes across words he cannot comprehend. Such words as "originally," "incompetence," and "desirability," and, in general, words of more than three syllables he can understand neither when he hears them nor when he reads them. But he understands so many words that he is able to carry on a conversation so well that his friends think he has entirely recovered.

The tests for the various forms of aphasia were very thorough, but are too voluminous for production here in detail. It will suffice, I think, to present a single specimen of each, taken at random from a great many.

When given letters and told to arrange them so as to spell words, he does so correctly when he is not word deaf for the word given.

Writing spontaneously. When told to write the alphabet he wrote it correctly, except the letters v and x, which he printed. In writing the alphabet he often had to stop and think, saying the letters over from the beginning, until he could get the one he wished to write, and then he was able to write it. He printed x and v because he had forgotten how to write them. When directed to write me a note about his health he wrote. "I am much better. I think I will soon be well."

Writing from dictation. When told to write, "This is the 21st of January," he wrote "This is the 21st of Janure," and said he couldn't think of the letters, though he knew it was incorrect. In writing other sentences he made similar errors in spelling. When told to write "When in the course of human events," he was word-deaf for "in," "human," and "events." He wrote "when" readily, and although I repeated "in" for him four or five times, he could not understand it, but asked if I said "a," "and," and "on," and then was obliged to give it up.

Repeating words from dictation. He can readily repeat words of one or two syllables. He cannot say "arithmetic." He can say each syllable after me, but cannot say them all together. It is impossible for him to pronounce other words of three or four syllables.

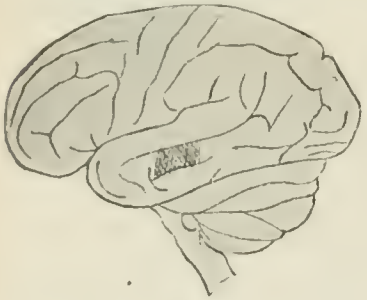

Fig. 2.—Case II. Thrombotic Softening of the Middle Third of the Second Temporal Gyrus. Deep shading indicates the position of the lesion.

Test for word blindness. He readily recognized all simple words when he saw them written or printed. Words of three syllables or more he could read but could not understand after he had read them, even when he read them aloud. This is, however, a condition depending upon a lesion of the higher auditory centre rather than of the higher visual centre.

The ability to name objects. He named all objects readily. The former difficulty which was so apparent when he first came under observation had entirely disappeared. Such articles as the telephone, the mirror, and various objects of furniture around the room, and the articles on my table and in my pockets he could name without hesitation.

This patient at first suffered from complete anomia, and was, and is, word deaf to a slight degree. His inability to comprehend some written and printed words and to write certain words from dictation is, of course, due to word deafness and not to word blindness. After a period of nearly a year from the date of his injury the anomia has almost, if not entirely, disappeared, while the word deafness, apparent at the very beginning, has not changed at all. The degree of word deafness from which he suffers is quite commensurate with the extent of cortical destruction in the higher word-hearing centre.

The second case is, as you will observe from your inspection of the brain which I now present for your observation, a case of softening of the middle third of the second temporal gyrus. It resulted from thrombosis. The patient entered the Charity Hospital on January 9, 1900. Of his family history nothing is known, but a few details of his personal history were secured for me by my house physician, who obtained them from the patient's friends. He was about forty years old and was a gambler. He was a man of good address, could read and write, talked well, and seemed to have a fair education. His memory, particularly for faces, was a matter of note. He seemed to be well up to three or four months before he came under our observation. During this time his memory became noticeably defective; he forgot people's names and faces, made errors in changing money and in playing roulette, which game he had charge of in the gambling-house. There were no ascertainable defects of speech.

When he entered the hospital he was in a semi-comatose condition. He could be aroused but did not seem to be conscious of his surroundings. The next day he began to regain consciousness, and in a day or two more his general intelligence seemed to be normal. From this time up to the day of his death, on January 23d, from cerebral hemorrhage, he seemed fairly bright. He always recognized me when I saw him, would shake hands with me, and always made tremendous efforts to express his feelings in spontaneous speech and to comprehend what I said to him. His face would flush with the effort, and finally putting his hand to his head, as if the strain had caused him pain, he would give up in despair. During the time he was under observation there was no motor paralysis in any muscle of the body, nor were there any disorders of sensibility. Many examinations were made until the exact conditions of aphasia were ascertained, and these were carefully verified by subsequent tests which also demonstrated the unchangeable character of the symptoms.

He did not show any evidence of the so-called motor aphasia. During the examinations he spoke many words, which, though they were seldom relative to the subject, were articulated plainly and distinctly and without effort. The special senses were unaffected so far as we could ascertain. He certainly heard with both ears, and seemed to see equally well with both eyes, and did not suffer from hemianopsia. Slight noises made on either side of him caused him to turn his head in the direction from which the sound came, and when he was spoken to even in low tones he invariably concentrated his attention upon the speaker. Anything handed to him from either side was quickly seen, and his hand would go out to receive it. The pupils responded well to both light and accommodation. He was almost completely word deaf. Even such simple commands as "give me your hand," "put the palms of your hands together," "pull up your bedclothes," were absolutely uncomprehended, though he readily understood what

I wanted him to do when the same things were communicated by signs, and immediately complied. When told to close his eyes, and the command was repeated two or three times, he did so; he also protruded his tongue, but only after being told to do so several times. Once when I told him to touch his eyes with his hand he passed the hand to his chin. Other speeches more complex in their scope seemed to be absolutely meaningless to him. When I spoke to him he would say "yes," and "no," or such words as "do tell," "any," "sometimes," "some," but all of them without any relevancy to the question asked. When shown a number of things together and told to select a certain one, he always took the one nearest to him. He was completely word blind. When given a book or paper he was as apt to hold it upside down as not, and when either was placed correctly in his hands, he could not read it. Written requests, as to pick up things, to put them down, to move parts of his body, to perform certain acts, were absolutely unheeded; but, as in former tests, he readily did as desired when shown by signs. When given a paper on which something was written he would take it in his hands, look at it intently, turn it around, then shake his head in negation, and hand the paper back without making any effort to obey the order.

Squares of pasteboard upon which were large printed letters were placed before him and arranged into words and sentences, but did not arouse any look or act of intelligence. He had absolute agraphia. When given a pencil and a piece of paper he took the pencil and placed it properly in his fingers, but did not write. When shown an object, such as a watch or a key or a knife, and it was indicated by signs and also by words that he was to write the name of the object exhibited, he could not do so. He could not write from dictation; he could not copy words, letters, numerals, or simple geometrical figures, such as squares and circles. He could not write spontaneously. He could not express his thoughts in spontaneous speech. He could, and often did, say a number of words, but they were uttered singly and disjointedly, and never in logical sequence. He could not name anything he saw, heard, or touched, though he was tested many times. He understood fairly well the uses of various objects, could feed himself, used his glass or cup properly, arranged his bedclothes to his satisfaction, and indicated by his handling such familiar objects as keys, match-boxes, nails, and other things that he knew their use. He was not by any means stupid. He took considerable interest in what was going on about him, would smile at many things he saw, and tried his utmost to understand and make himself understood, and ceased only after the effort gave him headache, or it appeared hopeless.

In this case of complete word blindness, agraphia, and almost total word deafness, with the consequent loss of voluntary speech, was not the diagnosis, during the life of the patient, of a lesion involving the superior temporal gyrus and the angular gyrus justifiable? And yet the inspection of the brain demonstrates that neither of these regions was diseased. The area of softening is confined to the middle of the second temporal gyrus, a region almost outside of the accepted word-hearing centre.

Another fact of great interest is that though the lesion was confined to the temporal gyrus word blindness was absolute, while word deafness possibly was not.

In Mills' case there was word blindness associated with anomia, and yet the lesion was farther from the higher visual centre than in my second case. Is it likely that in a case like this—word blindness with anomia—the real situation of the lesion in the third temporal gyrus would ever have been suspected without the actual demonstration afforded by the autopsy? In my first case the lesion was much nearer the angular gyrus than in either of the others, but there was no word blindness at all.

A careful consideration of these cases must enforce the conclusion that the presence of word blindness and word deafness, either alone or in combination, does not always imply that the lesion is to be found in the higher visual or higher auditory centres or in both, but that a lesion in any part of the speech area may so disorder the complex mechanism of the associated speech centres that any or all forms of sensory aphasia may be induced. This view of the case receives further confirmation by the conditions which almost invariably accompany the so-called motor aphasia. I refer to agraphia, the inability of the patient to tell the number of letters in a word and the number of syllables in words, the impossibility of combining numbers to any great extent, and the frequently coexisting amnesia. These factors are all evidences of the great disturbance which the partial or complete destruction of one centre induces in neighboring centres.

The ability of remembering names of objects and persons must be a part of the function of the higher auditory centre. It would, therefore, seem probable that any lesion destroying this area or a part of it, or, in fact, any part of the general speech area, may cause anomia. If this is so, and it seems to be, it can readily be understood how two such widely separated lesions as the ones observed in Mills' case and my own could both cause anomia.

The naming centre has yet to be found. It may be discovered some day, but at present it lies in the dreamland of theory only.

Antidotes for Iodism.—In a general article on iodism Douglass W. Montgomery says that iodism depends on a personal peculiarity of the patient, an idiosyncrasy, and nothing will absolutely prevent it where the tendency exists. There are some agents, however, which sometimes are capable of modifying some of the symptoms of iodism. They are belladonna, Fowler's solution, bromide of potassium, morphine, salol, sulphanilic acid, bicarbonate of sodium, chlorate of sodium. Belladonna is by far the best drug to relieve the coryza-like effects of iodide of potassium, and Montgomery generally gives five drops of the tincture with each dose of the iodide. Any other preparation of the drug, such as atropine, may be used. It may also control some other forms of iodism, as in the case mentioned, in which it prevented œdematous swelling in the neighborhood of the eyes. Fowler's solution is undoubtely the best associate drug to use when iodide of potassium causes indigestion. It is best given in one- or two-drop doses, just as one would prescribe it for indigestion.—*Medical Age*, October 25, 1900.

The Natural Process of Cure in Constipation.—Charles J. Hill Aitken reports in detail the progress of a patient who for more than three years suffered from dyspepsia with constipation. No drugs were administered, but he was put upon a simple, ordinary, well-cooked diet, which included fruit, vegetables, and fluids. He was ordered to go daily to stool after breakfast. His bowels became regular in their action, but any departure from his usual routine at once caused constipation. The intestinal muscles finally became so much more active that they reacted to the stimulus of food twice a day. To prevent the second motion which occurred at the inconvenient hour of 5 P.M., he was told to restrain his desire for evacuation if possible, but if not, to take chlorodyne. In time this treatment succeeded perfectly.—*The Medical Press*, November 14, 1900.

REFORMS IN BELLEVUE.

THE necessity for reforms in the management of Bellevue Hospital has been painfully apparent for a long time, and discussion on the subject has worn itself threadbare in vain appeals for the institution of radical measures tending toward the accomplishment of desired results. The medical profession, deeply interested in its welfare as a great institution for the care of the sick poor, has been pardonably jealous of its good name and reasonably anxious concerning the grand opportunities it should afford for the study and treatment of disease on strictly up-to-date scientific principles.

Its greatest handicap has been its association with politics. This has been proven in every part of its government from the appointment of an attending physician or surgeon to the employment of the lowest menial. A medical man may be ever so well qualified for a position, but if he has no friend in the councils of the dominating party, or is not connected with some medical school, his chances for preferment are almost invariably discounted.

Fortunately, the present medical staff is in every way a good one, but under the circumstances it is more a matter of luck than grace, and the argument goes no farther than to show that with the same principle at work exactly opposite results may be obtained at any future time. Even in the face of facts bearing at present on the right side of this question, the whole system is wrong and calls for radical change. The latter remark applies with particular force at this time to the male-nurse scandal, which, during the past week, has been so freely ventilated by the daily press. The revelations of the brutal treatment of patients in the insane pavilions and the alcoholic wards seem almost past belief. That the charges made by the helpless victims of these outrages are substantially based on facts is evident enough by the admission of Commissioner Keller and his prompt suspension of the guilty parties.

The possibility for the disgraceful occurrences in question appears to have been due to the lack of a proper supervision of nurse work and of the appointment of unfit persons for its performance. The mere graduation from a male-nurse training-school does not, in itself, guarantee the proper discharge of some of the most responsible duties of the calling. In no other sphere is it more necessary to control one's temper and suppress vengeful and cruel instincts than in the care of the wild maniac, or in the control of the wilful and perverse alcoholic. It would appear, however, that these nurses were positively cruel without provocation, and that the slightest excuses for the exercise of their assumed privileges of beating, cuffing, and partially strangulating and stupefying patients were in most instances eagerly seized.

All this proves the absolute necessity for constant supervision of ward work, and the great danger of delegating discretionary power to incompetent agents. The managers of lunatic asylums have long since learned this lesson, and having taken its precepts to heart have virtually abolished every form of cruelty in their institutions. Bellevue was so much behind in this respect that she required a gross and horrifying scandal to bring her to her senses.

The strange part of the recent development is that all these things should have been going on so long without the knowledge of the house staff, the attending physicians, or the commissioner of charities. It is not necessary to discuss here whose duty it was to know that this shocking state of affairs existed. It is perhaps a matter for congratulation that the real truth has come out at last. Commissioner Keller has done his part after the matter has been so directly and forcibly brought to his attention. The appointment of a special physician whose duty it shall be to supervise the nurses and be responsible for every other detail of ward management is a very important step, and will at least tend to prevent the barefaced brutality which has existed in time past. While the alcoholic wards are necessities for Bellevue, there does not seem to be any good reason why the insane pavilion should be used for other purposes than those of diagnosis, immediately after which a transfer should be made to a State asylum.

Commissioner Keller, now that he is impressed with the fact that Bellevue Hospital, as a whole, is not what it should be, has promised to examine the working of every one of its departments, with a view of suggesting necessary reforms. We doubt not that the result of his inquiries may throw much light in the darker corners, and may be very forceful arguments in favor of an entirely different system of government for the great charity hospital. To this end the proposed amendments in the charter will especially appeal. The more we discuss the question from this standpoint, the nearer will we come to the truth and the right. So long as politics rules our hospital, so long will preventable abuses show themselves. At times there will be attempts to remedy existing evils, but the lapsing into old conditions is inevitable when party interests are at stake and favorites must be served. There is really no excuse for politics as such in the management of our hospitals. As charity has no creed, science should have no political complexion. What is needed is a radical reform of the entire system, a government by an independent board and a management on a par with the model public hospitals elsewhere. All this is contemplated in the proposed amendment to the charter, and as a reasonable

reform measure it should commend itself to the approval of every unprejudiced and broad-minded citizen.

METALLIC SUTURES.

Silver wire as a material for sutures has long been popular, and the reasons for this fact are more or less self-evident. The material is easily obtained, is easily and certainly sterilized, and it is strong. Recently some actual antiseptic properties have been attributed to it from the alleged action of the fluids of the tissues forming in the track of each stitch a minute quantity of silver salts which, as is well known, are antiseptic. In a recent publication (Fiore, *La Riforma Medica*, August 28, 1900) the use of gold wire has been suggested for much the same reasons as are cited in favor of silver wire, except that no intrinsic antiseptic properties are claimed in the case of the more expensive metal. Several cases of hernia are reported by this writer in which wire of this metal has been used with satisfaction, but nothing is offered to show any superiority of gold over silver in this connection, so that, surgically speaking, the two metals may be considered together, and are, as far as we can judge, of about equal value. The good points of metallic sutures may be freely admitted, but the possession of these desirable attributes does not by any means prove that such varieties of suture give better results in conditions in which permanence of suture material is supposed to be necessary than are obtained with any other form of suture. In hernia, for instance, when metallic sutures are used, the primary results are often excellent, but other varieties of suture are also employed with excellent result, and it is good secondary and late results which are claimed for the metallic sutures by those who urge their use most strongly.

In one recently described operation for hernia, in this country, the use of silver wire is advocated for suturing in all stages of the operation, the claim being made that the silver wire being used in the deeper parts of the wound forms a network in the tissues against which the intra-abdominal pressure spends itself harmlessly. The fallacy of this argument in favor of the permanent utility of this form of suture is evident when we remember that these sutures, on which so much reliance is placed, are passed through relatively soft tendinous and muscular tissues, and that, no matter how strong the bridge or mattress of sutures may be, the whole structure can be only as strong as the anchorage of the sutures, which is in soft tissue easily and certainly cut through by any undue tension. This is only another illustration of the trite saying that a chain is as strong as its weakest link. Yielding tissues, dragged into an abnormal position by a wire suture, will return to approximately their original position, by allowing the suture to cut through far enough to restore the circulatory equilibrium in the minute vessels of the tissue in the line of tension of the suture, and if tension is increased the sutures will cut farther, so that in the operation for hernia which we have mentioned we cannot logically expect a really permanent result. The true function of a suture is to hold surfaces in apposition with as little tension as possible, until union can occur by the formation of new tissue between the surfaces. Even in bone it is very rarely necessary to use a metallic suture, though such use is often made, for we can never be sure that there will not be some sort of irritation, which will make a secondary operation of greater or less extent necessary in order to remove the offending unabsorbed suture. The present supply of absorbable suture material is by no means satisfactory in all particulars, but it is improving continually. The ideal suture is certainly that made of a strong, sterile, absorbable material which does not slip when tied, and these requirements are so nearly met in the best specimens of prepared catgut, that it is in this direction that we should seek improvement which may lead to perfection. We need not introduce complications by employing new materials which possess no advantages over what we already have. Gold wire is, no doubt, a good enough material to use for suturing in a circumscribed field, but we do not need it, and it is much more expensive than silver, the good qualities and disadvantages of which it has in equal degree.

EPILEPTIC INSANITY.

The association with epilepsy of mental changes of a degenerative character is a well-known clinical fact, the explanation for which is probably to be found in alterations in the nerve cells of the cerebral cortex, which are being detected with increasing frequency and facility by means of modern methods of fixation and staining. In a discussion of the subject of epileptic insanity at the recent meeting of the British Medical Association, Pasmore (*British Medical Journal*, September 22, 1900, p. 792) describes as the characteristics of epilepsy and epileptic insanity their markedly hereditary and periodic character, the existence of a normal mental state in the intervals between attacks, with the development of dementia only after varying periods, the occurrence of maniacal attacks before and after the epileptic convulsions, the alternation at times of such attacks with the convulsive seizures, or the replacement of the latter by the former. The maniacal attacks are of a sudden, impulsive, and dangerous character, being attended with violence, suicidal and homicidal tendencies, and destructiveness. It was pointed out that epilepsy with insanity on the one hand, and recurrent mania on the other, have in common hereditary transmission, periodicity of occurrence, the presence of a normal state in the intervals between outbreaks. Further, epilepsy may alternate with maniacal symptoms, while mania may precede or follow epilepsy. Maniacal attacks may entirely replace the epileptic state, especially if of the minor type. There is marked similarity between the mania associated with ordinary epileptic insanity and recurrent mania. For the foregoing reasons it is suggested that recurrent mania is an epilepsy of psychic type, and the designation psychic

epilepsy or epileptic mania is proposed for it. The condition appears to occur especially in those who exhibit a dual family history of epilepsy and insanity. The following clinical classification of the insanities associated with epilepsy is proposed: (1) congenital, including (*a*) idiocy (epileptic), (*b*) imbecility (epileptic); (2) idiopathic epileptic insanity, the ordinary insanity of epilepsy as met with in the adult; (3) hystero-epileptic insanity, found chiefly in young girls about the age of puberty; (4) psycho-epileptic insanity: (*a*) recurrent or epileptic mania, (*b*) transitory amnesia, and masked epilepsy.

UNBRIDLED QUACKERY.

Dr. Kenwood writes in English *Public Health* of "the ways that are dark and the tricks that are vain" of the numerous members of the quack fraternity. Referring to indecent advertisements in the papers he says: "The advertisements of the sexual quack tend to corrupt the sense of public decency and propriety. His other literature is invariably of the same type. Those who care to read this sort of stuff will find in it long columns of puffery, inuendo, and 'dirt' in the files of many papers, but mainly in certain Sunday and weekly papers, which are the most frequently read by those female members of the community who are most likely to be in need of that relief promised and least likely to hesitate in accepting the specious offers made to them. The printed matter sent out with these pills and potions leaves no doubt as to what the vendors wish to be understood as selling. They deliberately advertise their wares as capable of producing abortion, although they avoid using the actual word. They are mostly thinly-veiled invitations to purchase and employ the advertised agents for the purpose of procuring miscarriage. As to their actual power in this direction it appears that some preparations contain well-recognized abortifacients (pennyroyal, aloes, etc.), and the vendors evidently aim at acting up to their professions, but others are designedly inert. The literature of the trade often contains a warning to the effect that the remedy must not be taken by those expecting to become mothers. This is, of course, a transparent device undertaken to attract attention in order to sell the goods." Whatever may be the situation in Great Britain with regard to quackery, and from all accounts it is bad enough, we venture to say without fear of contradiction that the custom is not nearly so widespread or unrestrained as in this country. The laws in the United Kingdom are, on the whole, much more stringent with respect to an individual practising without a proper qualification than here. Doubtless means can be and are found to evade the law, but at least quacks do not get direct encouragement to pursue their calling as in many States of the Union. It is undoubtedly largely owing to this cause that the medical profession in the United States is to a certain extent in a perilous condition, and that a large number of the rank and file find it difficult to earn their daily bread. Competition among legally qualified physicians is sufficiently acute, but when in addition to this the unfortunate practitioner has to contend with a numerous and ever-increasing horde of illegitimate followers of the healing-art it cannot be said that "his lines are cast in pleasant places." In the Medical Record some few months ago attention was drawn to the question of nauseous advertisements inserted in religious journals, and we are willing to imagine that our animadversions have done some good. Many suggestions have been from time to time thrown out with the object of protecting the ignorant public against its own folly, but no really effective steps have been taken to stamp out or even to scotch the evil. In the mean time it would seem that the most the medical journals can do is thoroughly to ventilate the matter and to urge on every possible occasion the need of prohibitive legislation against unbridled quackery. Dr. Kenwood has the courage of his opinions, and "hits from the shoulder." He is to be congratulated upon his public spirit, the only pity is that there are not more like him in the medical profession.

News of the Week.

The Committee on Scientific Research of the American Medical Association announces that it has the available sum of $500 for the assistance of researches to be undertaken in the next six months, and that the money will be appropriated if applications be received within the month of January, 1901. Applicants should state clearly the character of the research to be undertaken, and the facilities at their command, addressing Dr. H. C. Wood, chairman, 1925 Chestnut Street, Philadelphia, Pa.

The German Hospital of Brooklyn.—On December 1st the board of trustees celebrated the first anniversary of the opening of this institution for the reception of patients. Appropriate speeches were made by several of the gentlemen present. The ambulance service of the hospital was considered and a large district was asked for by the hospital authorities. There are at present accommodation for one hundred and ten patients in the main pavilions and for ten in the isolation building.

The Philadelphia Neurological Society.—At a stated meeting held December 17th, Dr. D. J. McCarty exhibited a man presenting atrophy of the muscles of the shoulder girdle, with fascicular twitching, and possibly dependent upon amyotrophic lateral sclerosis. Drs. Charles K. Mills and T. H. Weisenberg exhibited three cases of cerebral hemianæsthesia and reported one case of hysterical hemianæsthesia, and made some remarks on differential diagnosis. Dr. William C. Pickett (by invitation) read a paper entitled "A Study of the Insanities of Adolescence." Dr. Charles W. Burr read a paper entitled "Astereognosis," in which he reported several cases presenting this phenomenon, which he looked upon merely as a symptom and dependent upon impairment of various forms of sensibility. Dr. F. Savary Pearce read a paper entitled "Neurasthenia: Especial Involvement

of the Sensory Neuron." He exhibited a man presenting analgesia of both sides of the face and of the perineum, together with abolition of the knee jerks and periodic laryngeal spasm, but with good station and preservation of the pupillary reactions. Opinions were expressed that the disorder was hysterical, and that it might be due to tabes dorsalis.

The Chicago Eye, Ear, Nose and Throat College will soon occupy a new building at the corner of Franklin and Washington Streets.

Typhoid Fever prevails widely in Galveston, the estimated number of cases in the city being about five hundred. It is believed that the infection is spread by the use of cistern water, the cisterns having become contaminated at the time of the great storm.

Influenza is reported to be exceedingly prevalent in Chicago. It is of a comparatively mild type. This is far from being the case, however, in St. Petersburg, where, a press despatch states, the influenza epidemic is so severe that the mortality returns for the week have been the highest for a decade. A meeting of physicians was summoned to discuss remedies, but scarcely half a dozen responded to the call, the rest being overworked, or themselves being victims of the malady.

The Hospital Ship "Maine" is now making her last trip, the British government having decided that it will not need the vessel any longer. The ship sailed from China on December 1st, with one hundred and eight sick and wounded soldiers. The *Maine* was fitted out by a committee of American women resident in Great Britain, and was employed first in South African waters and later was sent to China. She has been in commission somewhat over a year.

The State Tuberculosis Hospital.—It is reported that a majority of the trustees of the new State tuberculosis hospital have practically decided upon Raybrook, in Essex County, as an alternative site for the new institution, and will so report at the next joint conference of the Forest Preserve Board, the State board of health, and themselves. Raybrook is between Saranac Lake and Lake Placid, and on the railroad connecting those places. The advocates of the Dannemora site still contend that that is the best place for the hospital, the main argument urged being that the buildings could be erected by convict labor at little or no cost to the State.

Pan-American Medical Congress.—Among the social features of the Pan-American Congress to be held in Havana in February will be a grand ball at the Tacon Theatre under the management of the entertainment committee and an auxiliary ladies' committee. There will also be an excursion to the sugar estate of Señor La Coste near Havana. The guests will be carried on three government transports, and on arriving at the plantation will be shown the manner of growing, cutting, and grinding the cane, and of boiling and refining the juice, as well as all other points of interest in connection with life on a sugar plantation. Refreshments will be served on the estate on the transports during their return trip to the city. On another day there will be a parade of the police and an exhibition drill of the fire department in honor of the visiting members of the congress. Public receptions will be held by various officials, and many private dinners will be given by the Cuban physicians to their acquaintances among the visitors.

Rabies is reported epidemic in Rochester, many dogs having died recently of the disease, and a number of persons having been bitten by rabid animals.

Animal Diseases in Germany.—The Imperial German Health Office has published statistics of animal diseases in 1898, showing that twenty-four of the twenty-six German States were affected by anthrax. All the States were affected with foot-and-mouth disease and with wildfire among swine. Various other diseases prevailed to a considerable extent.

A New Englewood (N. J.) Hospital.—A new building of the Englewood Hospital, New Jersey, will be ready for occupancy in a week or two. The new building provides for a men's ward and a women's ward of twelve beds each, a children's ward of eight beds, six rooms for private patients, nine nurses' rooms, a sitting-room, a large operating-room, an upstairs dining-room, an isolating-room, a morgue, and a dispensary. The old hospital had long been inadequate for the needs of the community, for it accommodated only sixteen ward patients, and had but three small private rooms.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the navy for the week ending December 22, 1900. December 18th.—Assistant Surgeon R. E. Ledbetter detached from the *Constellation* and ordered to the *Monongahela*. December 21st.—Assistant Surgeon J. A. Murphy detached from the *Solace* and ordered to the *Don Juan de Austria*. December 21st.—Assistant Surgeon Jacob Stepp detached from the *Solace* and ordered to the Cavite naval station. December 21st.—Assistant Surgeon M. V. Stone detached from the *Yosemite Isla* and ordered to the *de Luzon*. December 21st.—Assistant Surgeon J. C. Thompson detached from the naval hospital, Cavite, P. I., and ordered to the *Solace*.

Obituary Notes.—Dr. Charles James O'Hagan, of Greenville, N. C., one of the oldest and best-known physicians in that State, died suddenly on December 19th, of apoplexy. He was a graduate of the New York Medical College in the class of 1856.

Dr. Charles S. Taft died in Mount Vernon, N. Y., on December 18th, at the age of sixty-five years. He was born in this city, and soon after graduation entered the medical corps of the army, where he served until about fifteen years ago. Dr. Taft was in Ford's Theatre, Washington, on the night President Lincoln was shot, and remained in attendance upon him with the other surgeons until he died.

Dr. Richard A. Wise, member of Congress from the Second Virginia District, died at his home in Williamsburg, Va., on December 21. The cause of his death was chronic nephritis. He was born in

Philadelphia in 1843. He served in the Confederate Army during the Civil War, and then studied medicine, being graduated from the Medical College of Virginia, Richmond, in 1868. After practising in Richmond for two years, he became Professor of Chemistry and Physiology at William and Mary College until 1880, when he resigned, and was from 1882 to 1884 superindentent of the Eastern Lunatic Asylum in the same city. Dr. Wise became active in politics in 1877, and was a strong Republican. He entered Congress in 1898.

Dr. George H. Elliott, of this city, died in Manchester, N. H., on December 17th, at the age of fifty-five years. He was a graduate of the Medical Department of the University of Denver in 1882. At the time of his death he was a Commissioner of Lunacy in New York.

Dr. Frederick Osborn Lloyd died at Hamilton, N. Y., on December 19th of cardiac disease. He was a graduate of the New York University Medical College in the class of 1885. He was a member for a term of the house staff of the Presbyterian Hospital.

Dr. John E. Losee, one of the oldest and most prominent physicians in Northern Dutchess County, died on Saturday at his home in Upper Red Hook, N. Y., aged seventy-four years. He had practised his profession for forty-seven years in that locality. He was born in Saratoga County, N. Y., and was graduated from the Albany Medical College in 1852. He served for several months on the house staff of the New York Hospital.

Dr. Ephraim Ingals died at his home in Chicago on December 20th, at the age of seventy-eight years. He was a graduate Rush Medical College in the class of 1847. He was an energetic advocate of higher medical education and did much practically to promote it, both as a lecturer in and contributor to the medical institutions of the city. At the time of the affiliation of Rush Medical College with the University of Chicago he gave $25,000 to aid in paying off the college debt and to found a chair of therapeutics and preventive medicine. He also gave $10,000 to the Northwestern University Medical School for the equipment of its laboratories. For a number of years he was associate editor of *The Northwestern Medical Journal.* He was one of the founders of the Republican party.

Dr. John Henry Fruitnight, of this city, died on December 18th, at the age of forty-nine years. He was born in New York on November 9, 1851, and after graduating in arts from the College of the City of New York in 1872, received his medical degree from the Bellevue Hospital Medical College in 1875. His attention was early turned to the diseases of childhood, and he soon won an enviable reputation as a pediatrist. Among the many organizations to which he belonged were the American Pediatric Society, New York Academy of Medicine, Medical Society of the County of New York, Society of Medical Jurisprudence, Physicians' Mutual Aid Association, Medico-Surgical Society, Northwestern Medical and Surgical Society, Good Government Association, and St. John's Guild. Of the last named he was a trustee and the consulting physician.

Progress of Medical Science.

New York Medical Journal, December 22, 1900.

The Diagnosis of Empyema in Children—By F. L. Wachenheim. The general appearance of the patient is often suggestive. A waxy complexion suggestive of sepsis is often present. Local inspection frequently shows relative retardation and diminution of the respiratory excursion on the affected side, occasionally obliterating or even bulging the intercostal spaces. Right-sided exudation may displace the apex beat. Fever with remissions and with sweating is present, while the pulse is rapid and of poor quality. In examining, we should percuss lightly, use the tactile sense to determine if possible a feeling of resistance characteristic of effusion. Percussion gives more or less dulness over the affected area, usually increasing downward; sometimes we obtain a tympanitic quality, but more rarely than in solid infiltrations. In the upper part of the thorax we obtain more or less dulness or tympanitic resonance, according to the condition of the compressed lung. The upper line of fluid can hardly ever be so sharply mapped out in empyema as in serous effusion, owing to its irregular limitation by adhesions and the usual concomitant pneumonic infiltrations. The determination, by percussion, of small effusions may be quite impossible. In empyema of the left side, dulness over Traube's space is very characteristic. Auscultation fails to give as accurate and reliable results as in adults. We usually have bronchial breathing, sometimes hardly at all diminished in intensity over the affected area; entire absence of respiratory sounds is very exceptional. It will be useful to remember that râles over the dull area speak decidedly against fluid, while faint and distant respiration denotes its probable presence. Friction sounds are exceedingly rare. If the child is crying, as it usually is, we may obtain more information. The voice over a pleuritic exudate is almost always faint and distant, and increased vocal fremitus is the best auscultatory sign we have for excluding fluid. Differential diagnosis is especially to be made from pneumonia and pulmonary abscess and gangrene. Exploratory puncture must be employed to settle the diagnosis in doubtful cases.

The Treatment of Supra-Condyloid Fracture of the Humerus.—By A. R. Shands. When the least doubt exists as to the position of the broken fragments of the broken bone, the *x*-ray should be employed. The broken ends should be brought into the best possible approximation and held there until union is firm; when it is impossible to obtain a perfect approximation, an incision should be made exposing the fragments to view, which, when put in the desired relation, the one to the other, should be secured there by some extraneous means. There are many conditions that may oppose this end, such as intervening tissue and muscular action, especially when the line of fracture is oblique. His preference is to drill a hole through the fragments and then to suture them in position with kangaroo tendon. When the fracture is oblique, he has found the tendency for the fragments to override each other so great that suturing did not do so well. In these cases he has left the drill in, which is a perfect method of holding the fragments *in situ*. He uses a drill that is long enough to project through the dressings, including the plaster of Paris. The operation being done under the strictest antiseptic conditions, the wound is closed and the drill is removed at the end of the second week; the little wound closes almost at once.

A Case of Superimposed Uvula.—By T. A. De Blois. The writer found on examining the throat of a young man that while the anterior pillars appeared normal and there seemed to be a perfectly formed uvula, there hung from the posterior pillar a second uvula almost masked by the first. This additional organ was removed with the galvano-cautery snare, whereupon the front uvula fell right back into the median line. The part removed appeared normal in structure.

The Combination of a Plaster-of-Paris Jacket with a Brace to Correct and Retain Correction of the Kyphosis of Pott's Disease of the Spine.—By A. M. Forbes.

A Report upon One Hundred and Seventy Cases of Appendicitis.—By R. T. Morris.

Intraspinal Cocainization from the Anæsthetist's Standpoint.—By S. O. Goldan.

Recrudescing Angina due to Friedlander's Bacillus.—By Emil Mayer.

Medical News, December 22, 1900.

The Treatment of Bronchitis in Infants and Young Children.—Samuel S. Adams believes that the treatment of bronchitis in infants and young children is largely dependent upon the etiology of the disease. The disease may be pri-

mary or secondary. It may be excited by cold or atmospheric conditions or by microbial irritants. It is usually sporadic, but may become epidemic. Prophylaxis consists in attention to the laws of hygiene. Attempts to abort bronchitis by a hot foot bath, free purging, and profuse sweating are seldom successful. Local measures are often beneficial. The turpentine stupe or mustard paste may be used. Inhalations of medicated vapors are valuable, *e.g.*, tincture of benzoin, eucalyptol, carbolic acid, etc. Expectorants are not well borne by infants. In the dry stage of the disease small doses of ammonium iodide in an agreeable menstruum, to which a few drops of syrup of ipecac are added, will hasten the secretion. Opiates should be withheld as long as possible, but when necessary a little codeine or paregoric may be given. Emetics are seldom indicated. Cardiac stimulants are required in most severe cases. Respiratory stimulants are required in a few cases. Jacobi's plan of flagellation, which causes the infant to cry, will relieve feeble respiration and passive pulmonary congestion. The general hot bath is good. Oxygen may relieve the feeling of suffocation temporarily.

Some Notes on the Treatment of Rheumatism.—Alfred Stengel states that in considering the question of rheumatism several fundamental facts must be recognized: 1. The tendency in many cases of this disease toward spontaneous recovery. 2. Complications are frequent and are more likely to occur in protracted cases than in those of short duration. 3. The complications are probably, as a rule, secondary to the joint disease and not to the infective lesion that was the primary focus. Of the drugs used in treating rheumatism the derivatives of salicylic acid occupy the first place. The rapidity and thoroughness of action indicate a relationship of the drug to the disease or some cases of the disease that warrants a place near to the remedies we term specifics. The simultaneous or separate use of salicylate of methyl, applied to the skin in the form of a ten-per-cent. or twenty-per-cent. ointment and covered with lint and oiled silk, is extremely satisfactory. In certain cases of polyarticular rheumatism which do not yield to treatment with salicylic acid combined with rest, general tonics are often effective. The writer has employed bichloride of mercury in small doses with good effect. Thus far no useful results from serum treatment have been obtained. The writer speaks also of casts and the fixation method for affected joints.

Report of Two Cases of Sporadic or Family Trichinosis; with Remarks on the Importance of Eosinophilia in the Peripheral Circulation as an Aid to Diagnosis.—By Hermon C. Gordinier.

A Rapid and Simple Operation for Gall Stones, Found by Exploring the Abdomen in the Course of a Lower Abdominal Operation.—By Howard A. Kelly.

Fatal Angina Pectoris without Lesions of the Coronary Arteries in a Young Man.—By T. E. Bullard.

The Surgery of the Gasserian Ganglion.—By Wallace Neff.

Boston Med. and Surgical Journal, Dec. 13 and 20, 1900.

The Results of Operations on Varicose Veins.—J. B. Blake considers that the conditions which will probably militate against satisfactory results are: old age or extreme debility; excessive or very extensive varicosity; occupations which, to an extraordinary degree, favor the development of varicose veins. Cases which may be cured by a thorough and careful operation are: Local varix, particularly if thrombosis has occurred, either in thigh or lower leg; extensive varix limited to a single venous stem; varicosities which are a bar to passing civil service, military or naval examinations; cases in youth and middle life; cases in which the development of the permanent varicosity was at least partially due to more or less removable conditions (flatfoot, garters, etc.). Operation, even if not entirely successful, will usually relieve such complications as thrombosis, hemorrhage, and ulceration. The usual conditions which follow unsuccessful operations are: Pain in and around the scar; general swelling and tenderness of the leg; development of varicosities above or below the operation scar, but not at the site of the operation itself. In all operated cases, general systemic as well as local treatment should be prescribed, together with exercise and the avoidance of a continued upright position wherever possible.

The Value of the Hot-Water Immersion Bath in the Treatment of Threatening Puerperal Eclampsia.—Charles M. Green believes that the hot-air bath is most appropriately used in the treatment of actual eclampsia. The hot wet pack is often successful in its results, but when circumstances permit its use the hot-water immersion bath more satisfactorily meets the indications. Not only does it produce profuse diaphoresis and reduce blood tension, but it acts as a marked sedative to the nervous system. The bath is easily administered to a conscious patient, the aid of a single assistant being sufficient. The water should be as hot as can be borne, and the patient should remain therein until profuse perspiration of the face shows that the sweat glands are in full activity. If the heart's action is at all weak, it is wise to administer brandy before immersion. When free perspiration has been induced the patient should be rolled in a blanket, placed in a warm bed, and covered with several blankets and perhaps a rubber sheet. The author gives a number of cases illustrating the good effects of these baths.

A Plea for Larger Doses of Antitoxin in the Treatment of Diphtheria.—John H. McCollom says that the clinical observation of nearly eight thousand cases of diphtheria justify the following conclusions: That the ratio of mortality of diphtheria per ten thousand of the living was very high in Boston previous to 1895. That this mortality has been greatly reduced since the introduction of antitoxin. That the percentage of mortality in the south department is lower than that of any of the hospitals taken for comparison. That since larger doses of antitoxin have been given, the death rate has been materially reduced, this reduction having occurred in the apparently moribund cases. That no injurious effect has followed the use of the serum. That to arrive at the most satisfactory results in the treatment of diphtheria antitoxin should be given at the earliest possible moment in the course of the disease.

Remarks upon Questions Arising during the Removal of Fibroids, with Especial Reference to the Technique of the Operation.—By Maurice H. Richardson.

Notes from the Neurological Department of the Massachusetts General Hospital. IV. Case of Myasthenia Gravis Pseudo-Paralytica.—By W. E. Paul.

A Contribution to the Therapeutic Action of Heroin.—By Bernard Lazarus.

Cases of Acute Oral Inflammation.—By John C. Munro.

Pericarditis with Effusion.—By George G. Sears.

Journal of the American Medical Ass'n, Dec. 22, 1900.

Symmetrical Development, or does Our Present School System Develop the Highest Powers of the Pupil?—E. Stuver concludes that: 1. The physical, intellectual, and moral powers of the pupils should be developed at the same time. 2. Parents and teachers should realize that in its development the child is an epitome of the development of the race and possesses many characteristics of the savage, barbarous, and semi-civilized races, and that instruction must ever be adapted to its changing needs. 3. The successful teacher must understand his own powers and limitations; he must understand the growing pupil and be able to put himself in the latter's place; he should have a more comprehensive knowledge of the laws of mental development, a better understanding of educational methods, and the best means of imparting instruction. He should be better paid and thus encouraged to make teaching a life-work. 4. More enthusiasm is needed and less routine; more original investigation and search after truth for the truth's sake, and less cramming for examinations; less talking and lecturing on the part of the teacher, and more time devoted to training pupils in systematic and logical analysis, and in clearness and accuracy of expression. 5. So many studies should not be pursued at the same time. The number-drill and arithmetic, together with other formal and abstruse work, should be greatly curtailed for the younger children and more time be given to the study of natural objects in their natural surroundings. 6. More time should be given to manual training. 7. Greater care should be exercised in promoting the health and proper physical development of the pupils. 8. All harsh and dangerous punishments should be banished from the schools.

The Antecedents of Organic Heart Disease in Children.—Frederick A. Packard from a study of seventy-five histories gleans the following facts: Rheumatism occurred in only 34 of the cases, chorea in 16, scarlet fever in 11, diphtheria in 8, while in 14 of the cases none of these diseases had been experienced by the child. If the small control series of cases can be taken as any guide, it would seem that measles, varicella, whooping-cough, and typhoid fever have little or no influence in the production of endocarditis. Therefore many instances of inflammatory lesions of the endocardium must be attributed to the slighter infections, such as coryza, various skin lesions, affections of the mucous membranes of the throat and nose, and the infections of the gastro-intestinal tract. The study of these cases emphasizes the necessity of a careful examination of the heart, both during and after slight infections.

The Use and Abuse of Zoological Names by Physicians.—Ch. Wardell Stiles states that: It is incumbent upon physicians to follow zoological customs in dealing with zoological subjects, as it is incumbent upon zoologists to govern themselves by the code of medical ethics in dealing with medical cases. He adds that the terminology in medicine is more or less subjective and based upon authority, without being bound by any regularly adopted national or international rules. In zoology the nomenclature is objective, based upon priority instead of authority, and subject to certain iron-clad rules and regulations, the result of a century and a half of study, and adopted by the national and international congresses; they are known as the code of nomenclature. To take a few examples of the liberties physicians take with zoological terms: Amibi coli is the technical name of a zoological object, and it should be written as above or Amœba coli; many write it Ameba coli, but this latter spelling is confusing and has no zoological authority. Tænia is the name of a genus of tapeworms and was proposed by Linnæus in 1758. Some write it Tenia, and others use Tinea, but Tinea is the name of a genus of lepidoptera, while Tenea is a genus of mollusks. Since in zoology there are several million systematic names, every genus must have a distiuct generic name, and every species in a genus must have a specific name distinct from the name of every other species in that genus. These facts make it imperative that the rigid rules which have been adopted governing the use of these names be enforced.

Angina Ludovici.—G. G. Ross declares that Ludwig's angina, or phlegmonous cellulitis of the floor of the mouth, is a comparatively rare affection. The tissue affected is rich in lymphatics and blood-vessels and contains the ducts of the subliugual and submaxillary glands. The disease may be either primary or secondary. In true angina Ludovici the infection is essentially primary. The point of entrance is in the mouth proper, and the disease manifests itself primarily in the floor of the mouth, and secondarily in the pharynx and larynx. The pathology is very similar if not identical with that of erysipelas. The organisms which have been discovered are the streptococcus and the staphylococcus. G. Leterier has collected thirty-one cases with thirteen recoveries. This series includes cases collected from old literature. The symptoms are marked from the onset, developing rapidly. They are very severe. Locally, there is a hard swelling, which spreads, however, till it involves the neck and face. Respiration is impeded. Deglutition becomes difficult or impossible. A marked general sepsis follows the local condition. The writer reports two cases. The clinical manifestations and pathologic finds so nearly resemble erysipelas that in an active surgical hospital these cases should be isolated.

Concerning Certain Apparently Injurious Constituents of Potable Spirits.—By Lauder Brunton and F. W. Tunnicliffe. The main points in which potable spirits differ *inter se* are with regard to their aldehyde, compound ether, fusel oil, and certain volatile base contents. This article has to do with a special aldehyde—furfural. This comes from a class of substances known as pentosanes derived from the cellulose of grain husks. Furfural can be detected in whiskey by adding to a drachm of the latter in a test tube an equal volume of water and then a few drops of a sodium-carbonate solution and then a few drops of aniline-acetate solution. If the tube be shaken up and allowed to stand a rose-pink color will develop. Injections of furfural in cats, dogs, and rabbits caused paralysis of the voluntary muscles, later clonic and tonic convulsions, with rapid and irregular breathing. Rapid recovery, however, was the rule. In addition, spirits containing the furfural and spirits free therefrom were given to animals with a view to comparison of effects. Speaking generally it was found that the return from what may be termed profound drunkenness in the cases of animals was more sudden and was accompanied by less secondary symptoms when aldehyde-free spirit had been given. The interest of these observations lies in the fact that these disagreeable symptoms, which seem analogous to those occurring in the human subject after too free potations, seem to be more referable to the aldehydes in the spirit, including furfural, than to the spirit itself or any higher alcohols. Fusel oil was present in the spirit both before and after distillation.

Dietetic Problems.—Abstract of the Purvis lecture by G. V. Poore. After alluding to some of the advances made in the dietary of the sick, the lecturer cautioned his hearers against looking too exclusively at the chemistry of food. Who when they ate considered whether they were taking too much carbohydrate or too much proteid? It was what they digested that did good, and this depended on whether it was savory and stimulating to the glands of the palate, and so forth. If a person sat down to a repast selected so as to contain a certain percentage of proteids it was very likely that the stomach would rebel. He thought that there was too much of this sort of thing and that physiological chemistry was doing itself no good by it. He could not help thinking sometimes that there were manufacturing firms who kept chemists very much as advertising tailors used to keep poets and for the same reason. In conclusion, Dr. Poore referred to "shop eggs" and to the difference between fresh and frozen meat. He also gave a humorous account of a visit to a village on a Saturday night where the grocers' shop-windows were filled with potted vegetables and where the smell from shops in which slabs of semi-transparent flabbiness were frying in oil could be appreciated a quarter of a mile away. Replying to a note that was handed to him asking for his opinion on the doctrine of not taking any meat, he said, "All flesh is as grass."

The Bowel-Lesion of Typhoid Fever.—T. J. Maclagan enumerates as the special points to be considered the following: (1) That the structures on which the typhoid bacillus exercises its specific effects are the solitary and agminated glands situated in the submucous coat of the small intestine. (2) That the change which it causes in these glands is inflammatory in nature and essentially consists in proliferation of their cellular and granular contents, with consequent swelling and hardening of the glands. (3) That this inflammation is generally sufficiently severe to cause gangrene aud sloughing of the affected glands. (4) That the direct action of the typhoid bacillus is limited to the glands of the submucous coat; and that it has no direct action on the mucous, muscular, or peritoneal coats. (5) That the sloughing process which destroys the glands necessarily also destroys the mucous membrane situated over them. (6) That with the process of sloughing and suppuration there come into play other and new morbid agencies, the various forms of cocci associated with these processes. (7) That to these new agencies rather than to the typhoid bacillus are to be attributed all the more serious complications and all the formidable symptoms, general as well as local, which are apt to show themselves during the third and fourth weeks of the disease.

A Peculiar Case of Purpura.—H. W. Spraight reports the case of a girl of nine whose whole body, including the face and the scalp, was covered with purpuric spots, varying from petechiæ to large ecchymoses. When she was going to bed on the night before, the patient had noticed some dark-red spots about her abdomen and thorax, and in the morning she found her body covered with purple spots. She felt, and appeared to be, in perfect health. She was not anæmic and had not been ill since she was four years old, when she had measles. There was no history of scurvy, rheumatism, or hæmophilia. Her family history was good. Next day hemorrhages occurred from patches on the limbs and continued during the following day, when hæmatemesis, hæmoptysis, melæna, epistaxis, and bleeding from the ears came on and continued until the second day after. During these three days the patient had no symptoms besides those of hemorrhage. On the following day the patches on the limbs began to fade, and five days later the skin looked perfectly clear and healthy. She was treated medicinally with ℥ ii. of Fowler's solution and ʒ i. of compound syrup of phosphate of iron, three times daily.

Suggestions for the Practical Treatment of Typhoid Fever.—W. Ewart says that until we shall find a germicidal cure for this disease our efforts must be confined to limiting the extent of ulceration, treating the ulcers, and obviating their giving rise to hemorrhage and perforation. He finds

danger in the stagnation of putrid fæces, relative inactivity of the liver, and distention of the thinned and ulcerated membrane. He finds it a good plan to keep the patients lying in bed so as to be slightly inclined to the left side. This position seems to facilitate the emptying of the cæcum. Internally he advises the administration of ♏ xx. of the liquor hydrargyri perchloridi (B. P.) with ♏ xv. of the tinctura ferri perchloridi flavored with orange or lemon given in an ounce of water every six hours throughout the attack and for ten days after to prevent relapse.

Notes of Two Cases of Foreign Body in the Air Passages.—By E. F. Syrett. In neither of the cases was the presence of a foreign body suspected, and in neither were there any urgent symptoms present. Case I. was that of a boy of thirteen years with evidences of involvement of entire right lung, whose condition went on to convalescence and who some two months later coughed up a cherry-stone which it was afterward learned must have been in the bronchus for thirteen weeks. Case II. was that of a woman of thirty-three years who had swallowed a wisdom tooth during its extraction by a dentist. It was expelled twelve days later.

A Case of Puerperal Septicæmia Treated by Anti-Streptococcus Serum; Complicated by Pulmonary Embolism, Perimetritis, and Axillary Abscess; Recovery.—By B. T. Read. The episodes of the case are sufficiently indicated in the title. Serum was injected in doses of 10 c.c. daily for over a week. The author believes that recovery in this case can be directly attributed to its use.

A Case of Morphine Poisoning Treated by Atropine.—By E. Ground. The patient was a man of sixty-one years who was supposed to have taken a little over four grains of morphine. In all about one-eighth of a grain of atropine was given, together with the use of potassium permanganate. Recovery ensued.

British Medical Journal, December 15, 1900.

A Clinical Lecture on Polyorrhomenitis, or Combined Serous Inflammations.—Frederick Taylor reports the case of a woman aged thirty-nine years who was admitted to the hospital for pain and swelling in the abdomen. It was a case of ascites, and the point to be determined was the nature of the origin of the peritoneal effusion. The choice in this case seemed to lie between tuberculous peritonitis and cirrhosis of the liver. Dulness at the base of the left chest was discovered which in a few days increased in an upward direction. It then seemed probable that the case consisted of a liquid effusion into the pleura as well as into the peritoneum. Thereupon the diagnosis of tubercle became more probable, and that of cirrhosis was out of count as explanatory of the whole case, though it was conceivable that an ascites from cirrhosis might coexist with an independent pleural effusion arising in some other way. Still another disease would account for the simultaneous existence of pleural with peritoneal effusion—heart disease causing passive effusions into both these cavities. But there was no evidence that the valvular apparatus of the heart was actually upset. Polyorrhomenitis may be acute or subacute or chronic, and the causes of these varieties are likely to be different. One cause of the acute form is the pneumococcus. There may be also a streptococcal or staphylococcal invasion. Rheumatic fever is sometimes the cause of the acute form. Now and then the tubercle bacillus is found, but it plays its most important part in relation to chronic and subacute inflammations, and is by far the most frequent cause of them. Polyorrhomenitis is more frequent in males than females, and the majority of the cases occur between the ages of sixteen and thirty. It is generally the peritoneum which is first attacked, then follow the pleuræ, as a rule the right one first. Pericarditis generally follows a pleurisy, especially a left-sided pleurisy. The inflammation may first involve one pleura, then the peritoneum, then the other pleura. The duration is variable. The prognosis in general must depend very much on the cause. Tuberculous peritonitis, *e.g.*, is probably fatal in more than half the cases; pleurisy is directly fatal in much less; but the associated lesion is not likely to be less fatal than the more fatal of the two operating alone. The treatment must be conducted on the lines of the treatment of the separate tuberculous lesions concerned.

Myokymia, or Persistent Muscular Quivering.—R. T. Williamson reports a case of this kind, the patient being a young man of twenty-one years. The quivering, which had begun in the muscles of the right leg, spread to the muscles of the limbs, trunk, and face. It was persistent. During the four weeks he was at the hospital there was no definite change. The writer has found eight cases in medical records, the ages varying from twenty-one to seventy-one years. All were males. In all the legs were most affected. The treatment in the cases in which recovery occurred was by warm baths and galvanism, by bipolar faradic baths, and by rest in bed. Sodium salicylate has been recommended. The cause and pathology of this peculiar affection are at present unknown.

Quinine Hæmoglobinuria.—A. G. Welsford reviews two interesting cases of this nature. It is of very rare occurrence. Hæmoglobinuria may be produced by several poisons, among which are potassium chlorate, carbolic acid, and arseniuretted hydrogen. It is in this category that quinine hæmoglobinuria must be placed.

Metabolic Fever.—By Arthur Todd-White.

Finska Läkaresallskapets Handlingar, November, 1900.

Gastric Myasthenia.—Max Buch regards myasthenia of the stomach as a lessened tone of the muscular tissue without stenosis. Insufficiency is not identical with, but may be caused by myasthenia. By auscultation and percussion the author has found that a myasthenic stomach changes position even when empty, its mobility being due to a slight gastroptosis. It is larger than normal, but there is not always insufficiency. The cause of the affection is to be found in local muscular weakness, usually following chronic catarrh, or in nervous troubles such as those which follow infectious diseases, typhoid fever, dysentery, cholera, peritonitis, etc., in which we find the local sympathetic plexuses inflamed and many nerve cells degenerated, or irritated conditions of the cœliac plexus or the sympathetic nerve.

Hernia of the Linea Alba.—A. F. Hornborg reports thirty cases due to subserous lipomata, traumatism, emaciation from tuberculosis or gastric cancer (loss of fat and general relaxation of the tissues), and, finally, to a general predisposition to hernia. The usual symptoms were digestive disorders occurring immediately after a shock or a fall, or there might be pain after muscular efforts, or in certain positions of the body, or after meals, etc., which always disappeared when the patient assumed a horizontal position. The indications for radical operation are many. The author was able to follow the after-history of twenty-two of the thirty operated upon. Seven died, twelve were completely cured, two had relapses—one in the cicatrix, the other in the neighborhood of the former hernia.

Dysentery in Finland.—F. E. Hellström observes that during the last century this disease has assumed a more and more benign character, as it has in all northern Europe. It is therefore often difficult to distinguish it from intestinal catarrh. He gives the mortality per 100,-

000 of the population, and notes that it is greatest when the temperature is highest in any given season. He gives tables of the mortality of dysentery in the various months, and at different ages. In early childhood there is the greatest mortality.

Temporal Hemianopsia due to Lesion of the Chiasm.—By Emile Juselius.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

POISONED BEER—GENERAL MEDICAL COUNCIL—THE COLLEGES, THE BIRMINGHAM CONSULTATION SCHEME—SURGERY OF THE BLADDER—THROMBOSIS AND SYPHILITIC FEVER—SPLENECTOMY—NEPHRITIS WITHOUT ALBUMINURIA—ROYAL SOCIETY.

LONDON, December 6, 1900.

BEER—arsenic in beer—peripheral neuritis and poisoned beer. If you could have heard our conversation all the week, you might have thought that beer monopolized all our thoughts. Unquestionably it has bulked largely in all the talk of the day. Even those who never drink beer cannot but feel shocked at the epidemic of poisoning about which I wrote to you last week, and the epidemic is spreading. One naturally expected a further crop of cases in the district affected, as the arrest of the consumption of beer, even if complete, would not stay the effects of that which had been previously drunk, and in many cases the time for the appearance of symptoms must have only just been reached. For the same reason, further cases may still be anticipated. But, what is worse than this, there is evidence that poisoned beer has had a wider distribution than was at first believed. Even London has not been without cause for alarm—one case of death having been found, by a coroner's jury, due to peripheral neuritis. The inquests held in the northern district have been adjourned for the purpose of analyses and some outcry has been raised against this as an attempt to shield those on whom the responsibility rests. The public does not understand why an analyst should not detect the arsenic in the tissues of a body as quickly as in the beer. Certainly the adjournments need not have been for so long a period. Meantime, the brewers have emptied thousand of gallons of their beer down the sewers and taken all precautions for the defence of their interests. Some of them have announced that in future they will use only malt and hops, and the public ask whether all should not be compelled to do so.

The matter is to be raised in parliament, and it is probable that a government inquiry will be insisted on. Perhaps it may result in some stringent measure against substitutes as well as adulteration.

Meantime I may note that in some cases the diagnosis has been confirmed by the detection of arsenic in the urine of the patients. This fact may go far to defeat the defence threatened that the poison has not been found in the bodies of those who have died of it.

The Medical Council has taken its full time and nullified the reports that the session would be a short one. It continued its work until Wednesday evening. To the surprise of some of its friends and critics, the council has shown some signs of backbone, but you need not run away with the idea that it is a fully developed vertebrate; a little stiff-neckedness is not a very portentous symptom. The council has actually resolved to adhere to its former resolutions on two subjects. One is the diploma in public health, which affects only a few persons, but it is intended to be a high distinction, and the council has determined to maintain the standard. The other subject is much more important—the conflict with the two royal colleges which stood over from last session. You will remember I gave you an outline of the dispute. The two colleges want to neutralize the effect of the five-years' curriculum by recognizing the teaching of science in grammar schools and even in board schools. The other corporations have fallen in with the views of the council, and the move of the two colleges looks like an attempt to outflank their rivals. Counsel's opinion has been taken on both sides, and the two agree no better than a couple of doctors. Litigation is most undesirable, and I hope the two colleges will fall into line with the other medical authorities now they have exploited their chartered rights; for, if insisted on, they might become "chartered wrongs." But will the council carry out the resolution to which it now "adheres"? Of any other body we might expect it. But, alas! we remember how, having threatened the Obstetrical Society, it climbed down.

Another subject on which the council has displayed unexpected firmness is the consulting institution at Birmingham, which I formally described. The "consultant" was summoned on the ground of the canvassing and advertising of this new aid society, and the case was conducted by Dr. Bateman of the Defence Union. The witnesses for the institution contradicted themselves as to whether it was a charity or not. Mr. Arthur Chamberlain, who seems to be the father of the scheme, came up and tried to bounce the council, and talked of the Birmingham practitioners as "street doctors," and of the "higher skill and knowledge" his plan would supply. But he exemplified only his own want of knowledge of the subject and his own self-importance.

The council listened and eventually informed the consultant that the charge had been proved, and that he would have to appear before them at the next session. The president informed him that the council regarded his conduct as serious, and in adjourning the case gave him the opportunity of reconsidering his position.

If the council adheres to this and the two other resolutions the profession will certainly rejoice in its new-found decision of character.

The surgery of the bladder occupied the attention of the last meeting at the Medico-Chirurgical. Sir Thomas Smith read a paper offering some suggestions for a possible improvement in the method of removing stones and morbid growths from the interior of the bladder. He brought the subject forward in order to hear the opinions of other surgeons before carrying out the suggestions in practice. The proposals were not very favorably entertained by most of the speakers, but received some support from Mr. Bennett and Mr. W. G. Spencer. The latter, indeed, said the suggestions commended themselves to him very strongly. Sir Thomas did not seem discouraged, for he remarked that when years ago he made analogous suggestions as to the removal of stone from the kidney by operation, the proposal was less favorably received than the present one. The new suggestion is briefly this: In view of the diminished risk of interfering with the peritoneal cavity, might it be worth considering whether the operation should be intra-peritoneal in cases in which it is desirable to obtain immediate union of the bladder wound? The precautions which would have to be adopted were pointed out, as well as the modifications in the mode of performing supra-pubic cystotomy. These included the adoption of the Trendelenburg position, distention of the bladder with air rather than fluid, opening of the abdomen at a higher point than usual, immediate closure of the bladder wound by suture, and after-treatment as required after traumatic rupture. In the discussion Mr. C. Lucas said supra-cystotomy is now very different to what it was when Sir H. Thompson revived it. Then the bladder was torn and drainage above the pubes used; now the bladder is cut. It was a great thing to clear the bladder thoroughly, but he saw no advantage in going through the peritoneum, and septic matter could not be excluded. Mr. Bruce Clark also insisted on the sepsis that was sure to occur. Mr. Freyer said the proposal opened up the question of supra-pubic operation, the ease and simplicity of which were its dangers, and the mortality was very heavy. Mr. H. G. Barling had collected statistics from six London and six provincial hospitals. Out of one hundred and eighty cases the mortality was twenty per cent., while lateral lithotomy averaged only five per cent. The supra-pubic operation was adapted only for very large stones or tumors. He did not think distention with air would be advantageous, and held that the intra-peritoneal plan must be very dangerous. Mr. Christopher Heath agreed with this, and thought it flying in the face of Providence to open the peritoneum when it could be avoided.

After this discussion Mr. W. G. Spencer described a mode of performing median perineal urethrotomy and cystotomy through a transverse superficial incision—a plan similar to that of Celsus, and which he recommended in certain cases. Mr. Barling's statistics were referred to by Mr. Freyer, who said lateral lithotomy was still employed in India and elsewhere, but Mr. Heath supported Mr. Spencer in the statement that it was obsolete. He said this subject came up periodically, and referred to Mr. Ward's paper in 1860, which contained much of what Mr. Spencer now said.

After this Dr. Bradshaw, of Liverpool, exhibited a crystalline deposit, previously undescribed, from an alkaline urine of a patient with dilated stomach, who was taking large quantities of magnesia. The crystals were of extreme tenuity and consisted of monohydric magnesium phosphate ($MgHPO_4$).

At the Clinical Society Dr. S. Phillips narrated a case of thrombosis of the inferior vena cava, iliac and femoral veins, setting in suddenly in an anæmic maid-servant aged nineteen, who had had symptoms of indigestion. She was seized with symptoms resembling perforation of gastric ulcer, and a few days later with swelling of the lower extremity, abdominal pains, etc. At the post-mortem the thrombosis was found, and Dr. Phillips regarded it as primary and infective.

Mr. Campbell Williams reported to the same society a case of late syphilitic intermittent pyrexia treated by mercury. Such cases do not seem to be so rare as might be supposed from the text-books not describing them; for several speakers mentioned having met with them. One of them said there was always a periostitis or some gummatous deposit as a cause for the constitutional disturbance, though it might not always be discovered. In Mr. Williams' case he had mentioned periostitis of the right clavicle as once detected. There were differences of opinion as to the treatment—some thinking mercury acted more quickly than iodide, others thinking the reverse.

Mr. Bland Sutton then reported a case of splenectomy for an enlarged and wandering spleen in a woman of thirty-four years, mother of seven children and pregnant at the time of operation. Since 1892 he has performed splenectomy nine times with two deaths. The seven survivors are in good health. He always avoids operating in cases of leucocythæmia. His rule is that the operation may be undertaken if the white corpuscles do not exceed twenty to the one thousand. He looks out for an accessory spleen so as to leave it if present.

Dr. Herringham then related a case of nephritis without albuminuria in a boy of four years, which he thought unique. The child was under observation in hospital and convalescent homes three months before the onset, so that scarlet fever could be excluded. At the post-mortem the viscera, including the kidneys, seemed normal, but microscopic preparations showed cloudy swelling in some convoluted tubes and albuminous plugs in many. An exudation was found in almost all the glomeruli.

Dr. S. West said he had seen several cases of this sort. It was not uncommon in infants, and up to two years; they had all the symptoms of renal disease without any albumin, and all got well. Dr. Ewart mentioned acupuncture, but Dr. Herringham said he had never seen a recovery after treatment by acupuncture.

The death-rate of London has been rising lately. The return for last week was 17.9. In the thirty-three largest towns it was eighteen per one thousand. The deaths from respiratory diseases were rather over the average.

Lord Lister's farewell address at the Royal Society was largely devoted to the recent discoveries as to malaria. He is succeeded in the presidency by Sir William Huggins.

SOME ASPECTS OF MEDICAL GYNÆCOLOGY FROM THE STANDPOINT OF THE GENERAL CONSULTANT.

To the Editor of the Medical Record.

Sir: "Next to the originator of a good sentence is the first quoter of it," dogmatizes Emerson. If "sentence," so much the more in the case of a scientific observation.

Therefore—having thought much and written some along the same line, and frankly envying the priority of succinct statement—I beg to throw into the black type of quotation the following from Dr. Beverley Robinson's masterful paper on "Some Clinical Aspects of Gout," published in the Medical Record, November 10, 1900:

"The most evident tendency (in medicine) is the all-pervading disposition to localize human ills. . . . From the laboratory point of view . . . micro-organisms are brought to the front almost invariably, and serve to explain whatever morbid sequences may arise. . . . The general pathology of other days saw undoubted facts also in atmospheric changes, constitutional peculiarities, habits of mind or body . . . now relegated frequently to the past. . . . And yet how true it is for the man of large observation and philosophic mind to trace many of our ills to purely functional disturbances."

The following is fruitful for those of us who work in gynæcological lines, and as a consequence fall more or less under the inevitable sway of the rule of environment, from which none are exempt:

"In some persons the gouty disturbance is apparently ushered in with functional upset of the liver. Under these circumstances I have known the urinary excretion to present nothing abnormal, or, at all events, not enough to be in any way characteristic of an impending gouty seizure. Rapid dyspnœa has occasionally followed, of a distressing type, which nothing organic would explain, and relief was obtained only when colchicum was duly administered.

"I have little doubt, it is true, that many gouty manifestations which appear to be functional . . . are of the nature of congestive or inflammatory disorders. *I have seen this notably in the prostate, the uterus and ovary, and rarely the intestines.* My views in regard to the probable rheumatic or gouty origin of not a few cases of appendicitis are already known to many. . . . For example, I do not believe because a tonsil occasionally becomes inflamed and enlarged under rheumatic or gouty influences, it should therefore be removed. . . . *What is true of the tonsil is true of the ovary*, with added force in the latter case because . . . more dangerous . . . and affecting child-bearing . . . and future changes of qualities and disposition of the woman."

The italics above are mine. Having pointed on every possible occasion to the frequency with which pelvic diseases of woman are associated with renal insufficiency, lithæmia, rheumatism, gout—and all the group of troubles included in passive congestion, faulty muscular development, and elimination—the above observations from another standpoint, to the same end, are welcome and significant.

A study of these medical aspects of modern gynæcology is sometimes dangerous because to cite surgical results seems to be making a criticism of the surgeons who operated. It would be impolitic for any one but a general consultant to utter the following:

"We are apt, I believe, also to regard an operation from the point of view of mere danger and not enough from the standpoint of what shall be the ultimate result. How many times have I seen patients operated on, even by surgeons of widest experience and most careful, conscientious judgment, who have few or no thoughts subsequently except to wish that they had never had recourse to the knife. Sometimes the patient's bodily disability or suffering has been greater than if they had really borne the trouble they already had and had become accustomed to."

Opposition to operations (other than plastic) in a large class of female troubles has become a fixed rule of practice with me, and I am happy to note a growing support from the profession. The class of cases is with me almost a hobby class—my environment pressure—and comprises the soreness in the venous system of women, the headaches and reflex neuroses, the abdominal ptoses, due to congestion, mal-elimination, and muscular debility, which properly applied régime almost invariably clears up. It is upon patients in this class that operations (other than plastic) so frequently fail to restore health. It is with patients in this class that local treatment is sometimes no more indispensable than it is for a periodical mammary tenderness: it is, of course, always an aid, but a minor detail of the general plan.

This statement, these quotations, all seeming agitations against surgery, may do great harm with those who do not understand and cannot discriminate between case and case. But while we may be justified sometimes in taking the esoteric position with the laity, no specialist is right in assuming this attitude toward the rest of the medical profession.

Yet the modification of standpoint by environment—as important as the personal equation in astronomical calculations—suggests that a routine warning should accompany every discussion of the medical side of gynæcology. It is an unpardonable error to delay surgery in a large and well-defined group of female troubles.

66 West Fiftieth Street, New York.

MALARIA AND MOSQUITOS.

To the Editor of the Medical Record.

Sir: Once more malaria and mosquitos. There is railroad being built from here running south and east to join the railroad of the Isthmus of Tehuantepec at a certain place. At a distance of 93 km. from Cordoba is a marshy plain with a few houses and no drinkable water. The place is called "Tierra blanca." When I went there I was greatly surprised not to find any mosquitos, and yet the place is a first-class malaria breeder.

F. Semeleder, M.D.

Cordoba, Mexico.

Treatment of Acute Alcoholism.—The expectant plan is the most rational. Opiates are dangerous, because they additionally derange digestion, and, acting as powerful cardiac sedatives, tend to paralyze the heart, and, finally, because they check elimination, interfere with the normal secretions and digestion. Sleep is never to be attained at risk or hazard to the patient, but is to be expected as one of the harbingers of a convalescence not to be enforced. In acute alcoholism, as in many other acute diseases, the vis medicatrix is fully adequate in most cases to produce the happiest results.—Dr. J. K. Bauduy, *St. Louis Medical Review*, December 1st.

THE NEW YORK ACADEMY OF MEDICINE.

SECTION ON MEDICINE.

Stated Meeting, Held December 18, 1900.

JOHN H. HUDDLESTON, M.D., IN THE CHAIR.

Treatment of Acute Alcoholism at Bellevue Hospital.—DR. A. R. BRAUNLICH read this paper. The cases treated were divided into three clases: 1st. Acute alcoholic intoxication. 2d. Delirium tremens. 3d. Alcoholic mania. On admission all cases received a cathartic consisting of calomel gr. x., bicarbonate of sodium gr. xx.

1st. Acute alcoholic intoxication. These cases were divided into two classes: (*a*) Those in the emotional and boisterous stage. These were given bromide of potassium gr. xxx., and chloral hydrate gr. xv., to be repeated in an hour if necessary. They were put to bed and next morning were discharged. Lack of room prevented the treatment of after-symptoms. (*b*) The stage of "dead" drunkenness. Here the patient was in a semi-conscious state or in a wholly unconscious condition. The stomach was evacuated and washed out with the siphon. External heat was applied and the patient rolled in a blanket, and, if necessary, stimulants were given, such as hypodermics of strychnine gr. $\frac{1}{30}$, or digitalis (fl. ext.) ♏ i. or ii. Patients were usually better in from six to twenty-four hours, or else they gave symptoms of another form of acute alcoholism, usually those of delirium tremens. These cases frequently developed an acute gastritis, for which small doses of morphine gr. $\frac{1}{30}$ were given, to be repeated every fifteen minutes to half an hour until they were able to retain small quantities of fluid, beginning with one drachm of milk or water.

2d. Delirium tremens cases. This occurred in chronic alcoholics, or in other persons after one or more excessive drinking bouts. These were the difficult cases to treat. The withdrawal of all stimulants from these patients was, at times, a very serious procedure, and he had seen cardiac failure supervene upon such a course, and œdema of the brain and lungs set in. The treatment of these cases was directed toward the circulatory apparatus. Alcohol was seldom given. The drugs which held first place for stimulation were strychnine in doses of gr. $\frac{1}{60}$ to $\frac{1}{20}$ and atropine in doses of gr. $\frac{1}{150}$. To produce sleep and rest, sodium bromide gr. xxx., and chloral hydrate gr. xv., were given, to be repeated in an hour if necessary. Morphine gr. ¼ and hyoscine gr. $\frac{1}{100}$ were also used. On account of these drugs producing depression, hypodermics of strychnine and atropine, and at times digitalis, had to be used. Patients who received large and frequent doses of the above and in whom it produced a fitful and unnatural sleep did not seem to derive much benefit, but appeared to be worse. He thought that a doctor who attempted to keep a quiet delirium-tremens ward fattened the grave-yard. For its soothing effect upon the nervous system and to reduce the temperature, the wet pack was successful in many cases. Patients were restrained as little as possible, the strait-jacket never being used. To prevent patients from leaving their beds their wrists were tied to the side of the bed, which allowed considerable freedom of movement. The question of food was an all-important one, and they were given milk and raw eggs by the mouth or rectum. Six to eight eggs a day was not unusual for a patient. So many eggs were used that a serious clash with the authorities had almost resulted. The unquenchable thirst present was treated by large quantities of water. Freshly prepared liquor ammoniæ acetatis was given in half-ounce doses every hour or two, and seemed to produce great benefit.

3d. Acute alcoholic manias. These patients were given the combination of morphine and hyoscine mentioned above, and this seemed to be the only combination that would procure them a moderate amount of rest. The neuritic cases, the epileptic cases, and epileptic-mania cases were transferred elsewhere. He wished to emphasize that alcoholics should be as closely watched as cases of pneumonia. Complications, as they arose, received appropriate treatment. In the anorexia, so common to alcoholics, a mixture containing tincture of capsicum ♏ x., tincture of nux vomica ♏ x., and tincture of ginger ♏ x., was given three times a day.

In closing his paper Dr. Braunlich mentioned some of the treatments followed by others. All the hypnotics had been tried. Some, on the advice of their visiting physicians, had tried exercise in the acute delirious stage, by walking the patient between two attendants until he was somewhat exhausted and able to sleep. Under this treatment the mortality was increased. The digitalis-and-capsicum treatment for delirium tremens consisted in the administration of one-ounces doses of the infusion of digitalis every four hours, for the purpose of eliminating the poison and stimulating the heart; with it were given large doses of powdered capsicum. A severe gastritis, of course, was a contra-indication. By giving an egg-nog before the capsicum the latter could usually be retained. The capsicum was supposed to increase the appetite. Lumbar puncture for wet-brain had been performed, but no conclusions as to its efficacy had been drawn. One of his successors followed this treatment, dividing his cases into three classes: (1) The emotional and boisterous alcoholics. These were quieted and subdued by bromide of potassium gr. xxx., and chloral hydrate gr. xv., repeated at short intervals if necessary. (2) Those on the verge of delirium tremens. These patients received solution of Magendie ♏ v., hyoscine gr. $\frac{1}{100}$, and strychnine gr. $\frac{1}{50}$. (3) Delirium-tremens patients. These received ♏ x. of solution of Magendie, gr. $\frac{1}{50}$ of hyoscine, and gr. $\frac{1}{30}$ of strychnine. His idea was to knock them out with one blow. He reasoned that one big dose of the hypnotic was not so depressing as frequent small doses and, therefore, not so apt to cause heart failure. He was a firm believer in the hot bath for delirium, although, not knowing its efficacy while on service, he did not use it at Bellevue. His own personal belief was that the important elements in the treatment were forced feeding and sufficient stimulation.

Classification and Asylum Treatment of Chronic Alcoholism.—DR. T. D. CROTHERS, of Hartford, Conn., read a paper with this title. He made the following divisions: 1st. The paroxysmal inebriates; 2d. The delusional inebriates; 3d. The senile and demented inebriates.

1st. The paroxysmal inebriates. This included the largest class of alcoholics. There were two divisions of this class of so-called periodical drinkers—one in which the spirit was taken at stated times, followed by a distinct interval of abstinence. The onset and termination of these periods comprised a distinct neurotic cycle; in one instance a man drank every ninety-one days, this period rarely varying more than four or five hours. The other division included those in whom the abstinent period and the time of using spirits were irregular and uncertain, depending upon causes both known and unknown.

2d. Delusional inebriates. These exhibited an increasing confidence in their power to control the desire for drink. This grew and became a veritable delu-

sion of strength of will and ability to regulate conduct under all circumstances and conditions. These cases were usually ascribed to outside causes which could not be foreseen. A certain number developed paresis, and it was difficult to say whether the early drink symptom was not due to the oncoming paresis or whether the paresis followed the poisoning from drink. Persons of this class were voluble, assertive, and dogmatic, and were imperious for help when suffering from the desire for spirits, and the moment this had passed the delusion of confidence and ability to care for themselves appeared again.

3d. The senile and demented inebriates. These, it was stated, drank without any motive or purpose, depending largely upon their ability to procure spirits. They were wanting in vigor and persistent energy to procure spirits, and while they seemed always alert to seize the opportunity to drink, were averse to any particular effort for this purpose. Most of these people were degenerate from birth; some were traumatic cases; some had suffered from profound wasting disease. Many persons of this class had been paroxysmal and delusional inebriates, and finally had come down to this senile stage.

Treatment.—In the treatment of these cases there must be control of the patient, and a change of surroundings and conditions of life. He must go away from home and all home associations and be placed among strangers. The author thought a hospital or asylum a long distance away, where the patient was unknown, the first requisite. If he belonged to the paroxysmal class, and the drink storm was beginning, spirits must be continued for a day or two. If the drink storm was ending, spirits could be removed at once. In the other two classes it was found most desirable to cut off all spirits at the beginning. The withdrawal of spirits should always be followed by calomel or a saline purge, with a prolonged hot-air or hot-water bath, followed by vigorous massage. Irritation following the withdrawal of the spirits could be readily overcome by strong infusion of quassia in ʒ ii. doses every hour until a profound disgust and sudden voluntary abstinence came on. The removal of alcohol and the breaking up of the demand for spirits were only a small part of the treatment. Giving remedies to produce a disgust and destroy a craving was simple, and could easily be accomplished. The use of strychnine after the quassia had been discontinued was very effectual. Nux vomica was often more valuable and could be used for a longer period of time. On the subsidence of the craving for spirits two conditions seemed to be very prominent—one of poisoning, and the other of starvation. The condition of poisoning required continuous treatment for a long time. The hot-air or electric bath seemed to be almost specific in these cases. The object to be attained was the rapid elimination of the toxins through the skin; also, of the waste from faulty assimilation and of the products of decomposition. The electric-light bath seemed to have the power of combining the effects of both light and heat in stimulating the surface circulation. The removal of the spirits often revealed conditions unsuspected before, which would require special treatment. Narcotics should be given with great caution. In his experience lupulin, lactucarium, valerian, and others of this class were more valuable than the stronger drugs. The general treatment, after the first acute stage was over, should consist largely of rest, foods, baths, and mineral tonics. The mental treatment was very important and effort should be made to foster and impress dominant ideas and direct the activities of the unstable mind along exact lines of living. One great object in the treatment was the removal of the causes and conditions for which spirits were taken. The full recognition of inebriety as a neurosis due to degeneration from inheritance and to physical and psychical injuries, also to the corroding and destructive influences of alcohol, must be noted. The principal points of treatment might then be grouped as follows: The patient should be placed in exact surroundings, the alcohol removed, and, if necessary, quassia or cinchona bitters should be substituted until all desire for spirits subsided. This was usually accomplished in a day or two. Then Turkish baths with salines and free elimination through the bowels and kidneys should follow. The baths should be given daily, with rest in bed and hot liquid foods. Beyond this the judgment of the physician should determine when narcotics were to be given, and when they should be abandoned; also, the value of strychnine or nux vomica or any of the tonics required by the conditions. The cessation of the drink craze was always temporary and the latter was likely to recur unless conditions of vigor and strength to overcome it were created. The medical judgment would determine the exact conditions and requirements in each case; not any particular drug or combination of drugs or so-called moral remedies, but a broad, accurate, scientific application of every rational means and measures which might be demanded.

The Treatment of the Drink Habit by Hypnotic Suggestion.—Dr. J. D. Quackenbos read this paper. He had been requested, he stated, to discuss the treatment of the drink habit by hypnotic suggestion, with reference especially to the technique, the class of cases that were amenable, the time limits of treatment, with the general results and the permanency of cure. In default of a more perspicuous philosophy, he had accepted the theory of a duplex personality, and explained the phenomena of hypnotism on the supposition of a double self, each self having a distinct state of consciousness. One of these states was called the primary consciousness, and for want of a better definition it might be explained as the self-luminousness of the objective mind, the inner light in which all the actions of the waking mind were made visible to that mind. The other, called the secondary consciousness, held those mental procedures of which, objectively, we knew nothing—all automatic actions. Each human being was thus an individual with two distinct phases of existence, a combination of two personalities which did not shade into each other—the personality by which he was known to his associates, which took cognizance of the outside world and consciously carried on the ordinary business of life; and a higher, more subtle personality, which science had demonstrated to be capable of acting independently of a physical environment, which intuitively apprehended, and which automatically controlled the physical and intellectual man in the line of its apprehensions. Through hypnotization this subliminal or submerged self, which spontaneously asserted itself in the natural somnambulistic state, was brought into active control. The technique adopted by him involved the conventional concentration of the visual attention upon some brilliant object, the securing of the patient's confidence in the physician's desire and ability to help him, and the usual sleeping suggestions, as an accompaniment of impression by the personality of the doctor. Dipsomaniacs, as a rule, were easy subjects, in that they yielded readily to the hypnotic influence and accepted unconditionally the suggestions communicated by the operator. Regular drinkers might be dealt with whenever they could be induced to sober. He had found it unprofitable to attempt the hypnotization of an intoxicated person. Periodic drinkers should be treated just before the close of the cycle of sobriety. Regularly recurring debauches have periods of varying length, the longest in his experience being three years; and he had satisfied himself that in some in-

stances a relationship existed between the abuse of tobacco and the oncoming of the irresistible thirst, the depressing effects of the nicotine instinctively suggesting resort to the antidote. Periodic drink-storms were usually forecast by significant indications—well known to the family and friends of the victim—irritability of temper, unreasonable suspicion, so-described "crank spells," abnormal restlessness, unaccountable depression. Immediately upon the appearance of these symptoms the patient should be treated by suggestion. Many such subjects recognized their danger, and sincerely wished to be cured. They were hypnotized and assured that they had lost their craving for beer, wine, or whiskey; that alcohol in any form would disgust them, and that they could not take it, could not carry the containing glass to their lips. The society of low companions was tabooed; the pleasures associated with drink and the glamour of the bar-room were pictured as meretricious and placed in vivid antithesis to the chaste delights of home life. The physical, mental, moral, and financial bankruptcy that accompanied dipsomania was held up before the view of the sleeper, and he was forced to the conviction that, begotten of this apprehension, had come into his soul an abhorrence for drink and all that it stood for. The subpersonal mind was then directed to the vocation or the avocations, or both, as circumstances suggested, and a career of wholesome activities and satisfactory successes was imaged as the legitimate result of the abandonment of the compromising habit. It would thus be seen that hypnotic suggestion was of the nature of inspiration. It was a summoning into control of the true man; an accentuation of insight into life and its procedures, a revealing—in all its beauty and strength and significance—of infinite, absolute, universal, and necessary ethical truth; and a portraiture of happiness as the assured outcome of living in consonance with this truth. It was not a mere pulling up of weeds by the roots, as Horace Fletcher described it in "Menticulture;" but it was a sudden overshadowing and starving out of character defect and mental weaknesses by a tropical growth of ethical energy which sought immediate outlet in the activities of a moral life. The patient freely expressed his best self post-hypnotically, without effort, from a plane above the will—the plane of apprehension and spontaneous control along lines of thought and action that were high and true. Such inspiration could not be mere lip-work or rote lesson. It implied a belief in the suggestions offered, an eloquent and incisive manner born of the courage of conviction; in short, a reciprocal transfer of personality. Perfunctory speeches were of no avail, for the mind of the mesmerized was endowed with supra-normal insight, instantaneously detected the disingenuous, and rejected the counsel of an uncandid or lukewarm guide. In practical hypnotics, the best thing one had to give was himself. A sine qua non of success was the consent of the patient, an honest desire on his part to reform. Habitual drinkers, those who "soaked," as Goldsmith described it, did not, as a rule, wish to be cured. They enjoyed indulgence in alcoholic fluids and the false pleasures that attended it; and about ninety per cent. of them, women as well as men, resented the approaches of those who desired to save them. Sometimes, when no other form of appeal was effective, they might be frightened into a realization of the fact that constant use of alcoholic stimulants would result in organic changes in the liver, kidneys, and brain; or by lowering the general powers of resistance and at the same time irritating the bronchial tubes and the lungs, through which the alcohol was in part eliminated, markedly predisposed to pneumonia and pulmonary consumption. In fact, immoderate drinkers might, in sober intervals, be made to realize, not only that they were physically depraved, but intellectually deteriorated as to the faculties of memory, attention, concentration, judgment, and that they were deficient in business tact and in the general address essential to success. Once apprised of their enervated mental condition, they honestly desired to correct the habit, but could not of themselves, the craving simulated a mania. Under these circumstances it was comparatively easy to persuade a patient to accept treatment, and a rescue might be effected in a week's time. But the treatment must be persisted in for a much longer period, the tendency being to abandon it too soon because of a belief in cure. A patient, whose language he quoted to show his confidence after a single treatment, subsequently fell: "I am getting on splendidly, and my better self still has complete control, causing me to feel that I shall never return to those miserable times again, for I have not the slightest desire in the world for anything in the alcohol line." It was quite common for patients to express themselves similarly after the first series of suggestions, and for relatives to write that they were "astounded at the result." But if some unlooked-for pressure of passion and allurement was brought to bear on the self-confident subject, he was almost sure to yield. An inebriate patient who went two months in New York without experiencing the slightest desire for alcohol, and was proof against all solicitations to enter a saloon, encountered in Philadelphia a combination of business disappointments and temptation that proved irresistible. Could the operator foresee such a contingency, he might avert it. It was not claimed that the tendency to relapse was obliterated by hypnotism. The cure might or might not be permanent, as was the case with rheumatism, quinsy, bronchitis, intermittent fever with its distinct germ and distinct specific. No physician was asked to guarantee a patient against a recurrence of tonsillitis, especially when the patient deliberately exposed himself to the appropriate conditions for a relapse. No more could be expected of the physician suggestionist, who was not a miracle-monger The utmost he could do in a prophylactic line was to reject all compromises in his treatment, suggest total abstinence, forbid exposure to temptation, and render insensible to the psychology of the saloon. Experience proved that it was always better to deal, in drink-habit cases, with the nearest of kin rather than directly with the patient, who naturally overestimated his powers of resistance. Courting a conflict with the demon of drink, as many did, was playing with fire. A dipsomaniac who was sent to him from Paris a year ago, for treatment at his summer home, was practically cured in a week. He returned to New York, and there insisted on living in a cabaret. The inevitable soon occurred. There were cases in which the drink habit had become so ingrained that the early promise of post-hypnotic suggestion was gradually brought to naught by continual returns, seemingly inexplicable, of the uncontrollable craving. The automatic mind struggled in vain for mastery of a habit, which had not only evolved into a second nature, but was forever converting an unnatural appetite into a fiery passion. Suggestion in such an event should be supplemented by appropriate drugs, and in some instances by discipline. The physical side must not be lost sight of. While hypnotic suggestion might regulate a disturbed metabolism in the nerve organs or check atrophic changes in cell protoplasm, it could not be expected to repair lesions in the blood-vessel sheaths or suddenly atone for the results of an exaggerated destructive metamorphosis in the nerve-cell bodies. Fortunately, the damage to the cells was measurably reparable by discontinuance of the poison and judicious administration of nourishment. Therefore, in his treatment, alcohol was immediately withdrawn, stimulating liquid

food was given every two hours for a day or two, a phospho-glycerite was administered with a view to refining the quality and increasing the quantity of the lecithin, also a tablet containing strychnine, nitroglycerin, and capsicum, fluid extract of coca if required, a valerianate to control undue nervous expression, and bromide and chloral to induce sleep. In the insanity of extravagant drinking, coupled with chronic nicotine poisoning, suggestive treatment might sometimes be delayed with advantage until after the compulsory reduction or withdrawal of the artificial stimulant. Patients who, to rid themselves temporarily of the importunity of relatives, accepted an institutional life, with mental reservation as to their habits at the termination of the period of treatment, were proper subjects for suggestion while in sanatoria. "The tongue has taken the oath, but the mind is unsworn." Under such circumstances, with the craving in lull, the subliminal self might be successfully impressed. The views advanced were based upon an experience with some forty cases, extending over a period of nearly two years. Of these cases, some of which were quite recent, fifty per cent. had not returned to drink, approximately thirty-three per cent. had been lost sight of and could not be heard from, approximately seventeen per cent. were known to have relapsed, without rebound. More than half the latter were practically hopeless from the beginning. The success of the treatment bore a distinct relation to the amount of injury already inflicted upon the brain cells and the accompanying mental deterioration. Its advantage consisted in the rapidity of restoration to self-control without the necessity for effort, without the physical discomfort or suffering that usually accompanied abandonment of the habit, and most conspicuously without the breaking of family ties and the enforced absence from professional or business duties that were implied in sanatorium treatment.

Medical Items.

Diseases of Samoa.—Dr. Edward M. Blackwell, assistant surgeon U.S.N., discusses in the report of the surgeon-general, U.S.N., the disease of the Samoan Islands. He says concerning the maladies which attack the natives of the harbor of Pago-Pago, Tutuila Island, that "the most common of these are bronchial, rheumatic, neuralgic, and digestive troubles. The first three are probably due in great part to the fact that the natives get their clothes wet very often, and allow them to dry upon their bodies. Those who wear least clothes are generally least affected. The digestive troubles are probably due to the character and mode of preparing and eating their food, and to sedentary habits. Blindness in one eye is very common, and it is generally due to ophthalmia in childhood, which has been neglected. The cornea is opaque, and the lens generally bulges forward and adheres to it. As a rule, all the children have a peculiar eruption, which I have been unable to diagnose. It generally spreads over the whole body and limbs. It is macular, papular, vesicular, and pustular in the different stages, and often in the later stages there are large foul ulcers. The natives think it is a necessary disease of childhood, and if it is late in making its appearance they sometimes inoculate the child with virus from the pustules of another child. There appears to be very little constitutional disturbance attendant upon it. . . . A lady who lives at Faga-Toga has practised considerably among the natives and with very good results. She has had no medical education, except what she has picked up from a United States dispensatory, and from surgeons who have visited the harbor. She keeps the commoner drugs, and appears to understand their uses fairly well, and to prescribe them intelligently. I have seen several fractures she has reduced and treated with very good results. Two amputations that she has performed, one of the arm and one of the forearm, have come under my observation, and the results were very good. She had native assistants, and the only instruments she had were a hand saw and a razor."

A Toe for a Finger.—Nicoladoni has recently published a case in which a toe was surgically substituted for a lost finger. Four months before operation, the patient lost his right forefinger by accident. The second toe was so divided that an attachment still remained to his foot by means of the soft parts, and the toe was applied in the place of the absent finger, the parts being kept in position by a plaster cast. For twelve days a gradual severance of the connecting bridge of tissue was carried out, until a complete separation was effected. The whole toe retained its vitality, and it is further reported that it has developed sensibility, although the power of movement has not yet been established. Nicoladoni hopes that it will occur. This is his second case of the kind.—*Medical Times and Hospital Gazette.*

A New Detention Hospital for Minneapolis.—Philanthropic citizens of Minneapolis have generously subscribed $24,000 for a new detention hospital on the city hospital grounds.—*The Medical Dial*, December.

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended December 21, 1900:

		Cases.	Deaths.

American Medical Editors' Association, 19.

American medicine, 201.

American Proctologic Society, 112.

American Public Health Association, 753.

American Therapeutic Society, 259.

Amniotic fluid, scanty, as a factor in procidentia of the cord and fœtal disorders, 966.

Amputation, construction of stumps in, 833; osteoplastic, 427.

Amyl salicylate, therapeutic use of, 949.

Anæmia, breathlessness in, 855; diagnosis and treatment, 657; etiology of progressive pernicious, 784; limits of heart dulness in, 624; lymphatic, in children, 583; pernicious, 227, 633, 824; pernicious, and its relation to inheritance, 841, 909; pernicious, diseases of the organ of hearing in, 707; pernicious, following on traumatic stricture of the small intestine, 183; pernicious, Hunter's treatment, 193; pernicious, with spinal symptoms, 826; phenylhydrazin in, 264; rapidly progressive, 056; recognition and treatment of the, 264.

Anæsthesia by chloroform and ether, arterial pressure in, 428; by nitrous oxide and ether, 740; general, 24; prevention of nausea and vomiting during, 984; spinal, 344, 508, 521, 561, 577, 601, 615, 624, 674, 714, 740, 744, 750, 791, 799, 828, 862, 868, 937, 967, 992.

Anæsthetics, effects of certain, upon the kidneys, 545.

Anasarca, surgical treatment of, 733.

Anderson, John, death of, 388.

Anderson, William, death of, 830.

Aneurism, excision of, 626; gelatin in the treatment of, 185; multiple, 902; mycotic embolic, 427; of the abdominal aorta simulating chronic colitis, 226; of the aorta, galvanic treatment of, 951; of the aorta, treated by gelatin, 904; of the arch of the aorta, 196; of the renal artery, 624.

Angina Ludovici, 1020.

Angina pectoris, 941; nervous disturbances in the domain of the brachial plexus in, 346; oxygen in, 948.

Angiotribe in vaginal cœliotomy, 143; use of the, 62.

Anglo Saxon race, degeneration of the, 960.

Animal diseases, 757.

Ankle clonus, 656.

Ankle joint, rupture of the anterior annular ligament, 583; sprains of the, 267.

Ankylosis, universal, 795, 997.

Ankylostomiasis, 358; in the Leeward Islands, 266.

Anosmia, 987.

Antagonism of diseases, 439.

Anthracene, death from, 539.

Anthrax, a case of, 625; connection of the Cyprus sphalangi with, 359; immunity of the dog against, 786; local injections of pure carbolic acid in, 453

Antisepsis, Lord Lister on the development of, 665.

Antistreptococcic serum, employment of, 225; some results of, 146.

Antitoxin, a plea for, 159.

Antivenene, 677.

Antivivisection in Sheffield, 360.

Antrum, treatment of empyema of the, 467.

Anus, temporary artificial, 113.

Aorta, dissecting aneurism of the, 105, 115; ligature of the abdominal, 387

Aphasia, two unusual cases of, with special reference to the naming centre, 1010.

Apomorphine as a hypnotic, 827.

Apoplexy, diagnosis of, unaccompanied by motor paralysis, 103; high temperature following, 465.

Appendicitis, 799, 955; and typhoid fever, diagnosis between, by means of iodine reaction, 861; an unusual symptom of perforative, 576; conservatism in the treatment of, 339; diagnosis of suppurative, 652; facts concerning, 466; fistula after operations for, 220; fulminating, 713; hemorrhage due to rupture of adhesions following, 924; in infancy and childhood, 425; intestinal obstruction complicating, 653; in women, 870; latent, 905; latent, and inflammation of the right broad ligament, tube, and ovary, 531; medicinal treatment of, 173; neuroses in relation to, 828; peculiarities in, 996; pseudo-, 16; rheumatism in relation to, 830; significance of pain in, 80; some cases of acute, 688, 716; subphrenic abscess following, 104; the blood in, 633; treatment of, 155; typhoid, 142; when and why to operate in, 55, 224.

Appendix, anatomical researches in regard to, 427; cancer of the, 347; elimination of the inflamed, gangrenous, or perforated, from the peritoneal cavity, 940; safest method of removal of the, 264.

Arcularius, Louis, death of, 21.

Argyll-Robertson pupil, significance of the, 583.

Army, veterinary corps for the, 981.

Arrhythmia cordis, complicating fibroma uteri, 224.

Arsenic, accidents of medication with, 827; in a popular purgative, 360; in beer, 898, 944, 1022.

Arterial duct, persistence of the, 146.

Arteries, suture of, 386.

Arteriosclerosis, 510; senile, 109; treatment of insomnia due to, 940.

Artery clamp, a modified, 78.

Arthritis, gout, and rheumatism, differentiation of, 17; infective, iodide of iron in, 142; tuberculous, 673.

Artificial respiration for 14½ hours in a child one week old, 905.

Ascites, chylous, 23, 380, 795.

Ashhurst, John, obituary of, 61.

Aspergillosis, 386.

Aspirin, therapeutics of, 145.

Astasia-abasia, hysterical, 949.

Asthma, cause, nature, and treatment of, 663; pathogenesis and treatment of, 950; relation of, to nasal disease, 535; renal, 655; treatment of, 666.

Ataxia, acute, 877; hereditary cerebellar, 476.

Athletics barred from Chicago University, 160.

Atriplicism, 574.

Atrophy and development, 743; progressive muscular, 475.

Atropine, notes on, 518.

Attachés, medical, to German embassies, 920.
Audition, blood circulation in the head in relation to, 753.
Autotoxæmia, 234; diagnosis and treatment of, 265; gingivitis from, 303; in nervous disease, 534; tetany dependent upon, 910.
Azoöspermia, 508.

B

Babinski's sign, diagnostic value of, 775.
Baby, the twentieth century, 959.
Bacillus aerogenes capsulatus, morbid conditions caused by, 183.
Bacillus coli communis in drinking-water, significance of the, 324.
Bacillus xerosis in progressive phlegmon, wound infection, and otitis media, 706.
Bacteria, demonstration of the capsule, when grown in non-liquid media, 545; influence of the temperature of liquid hydrogen upon, 225; prehistoric, 120.
Bacteriology, present status of, 460.
Bainbridge, William Seaman, analgesia in children by spinal injection, with a report of a new method of sterilization of the injection fluid, 937.

Cicatrix, cancerous degeneration of a, 961.
Cirrhosis of the liver, 834; and pancreas with diabetes and hæmachromatosis, 950; Hanot's, 788; nature and distribution of new tissue in, 950; the pancreas in, 268.
Claiborne, J. Herbert, three cases of specific basal meningitis, with special reference to eye symptoms, 190.
Clavicle, fracture of the, resulting in rupture of the suprascapular artery (?), 973.
Clavicular crutch, 717.
Cleft palate, closure of, by lingual implantation, 22.
Clinical opportunities in American medical centres, 36, 86.
Clowes, Joseph Washington, death of, 423.
Club-foot, open incision for, 317.
Cocaine and hypnotics, antagonism between, 576.
Cocainism, 628.
Cod-liver oil, addition of iodine and phosphorus to, 665.
Coeliotomy, blood changes following, 24; dressings left behind after, 184; following ventral hernia, 711; objections to bilateral inguinal, 549; one hundred consecutive cases of, without a death, 104; some considerations on, 716.
Coffee, adulteration of, in Europe, 479.
Cohn, Robert D., treatment of laryngeal tuberculosis, 970.
Cold feet, treatment of, 348.
Cold, influence of intense, upon bacteria, 225.

Colds, potassium bicarbonate in, 784; prevention and treatment of, 623; production of, 176.
Colic, causes of, 218; renal, faradic electricity in, 235.
Colitis, muco-membranous, 918; mucous, sodium sulphate in the treatemnt of, 864.
College of Physicians of Philadelphia, 780, 982.
Collins, William T., death of, 823.
Colon, dilatation of the, 622.
Colpocœliotomy, posterior, for lesions of the adnexa and uterus; its indications and technique, 247.
Coma, diabetic, 840; traumatic diabetic, 950.
Compensation, processes of, 828.
Confederate States, Association of Surgeons of the, 102.
Conjunctiva, diphtheria of the, 143; infection through the, 425; injections beneath the, 546.
Conjunctivitis, demodex folliculorum in relation to, 864.
Connell suture in intestinal anastomosis, 717, 739.
Consanguineous marriages, undesirable, 183.
Conservatism in surgery, a case illustrating, 991.
Constantinople, letter from, 708.
Constipation, bearing of the ileo-cæcal orifice on, 469; natural process of cure of, 1013; proctitis as a factor in, 114; treatment of, 557, 786.
Consumption, Canadian league against, 518; deaths from, 839; fat food as a preventive of, 559; isolation of convicts with, 857; racial tendency to, 513.
Consumptives (see also *Phthisis*, *Pulmonary Tuberculosis*, and *Tuberculosis*), care of, by the city, 746; isolation of insane, 578; Liverpool sanatorium for, 778; marriage of, 760; New York State Hospital for, 579, 659; open-air treatment of, in southern Brittany, 120; plea for, 639; spray for room occupied by, 797; State sanatoria for, 360, 663; treatment of, at home, 581.
Converse, George M., a case of tetanus treated with antitoxin, 194.
Convulsions, 50.
Convulsive states, 535.
Cool, art of keeping, 543.
Copper, food poisoning by, a fallacy, 679; poisoning by, 731, 828.
Corning, J. Leonard, Corning's subarachnoid cocaine anæsthesia, 791; some conservative jottings apropos of spinal anæsthesia, 601.
Corynebacterium lymphæ vaccinalis, 105.
Costello, Henry J., death of, 260.
Coup-de-foudre, 428.
Courtney, J. E., two cases of self-castration, 396.
Cousins, marriage of, 158.
Craig Colony for Epileptics, 737.
Craniectomy, Lannelongue's, 63.
Crazes, psychology of, 320.
Creed, Cortland Van Rensselaer, death of, 260.
Cremation in Spain, 539.
Creosote pills, 393.
Crete, leprosy in, 102.
Crime, prevention of, 35; sexual function, and insanity, correlation between, 698.
Cross-eye, effect of, upon the general health, 90.
Croup, symptoms of, 175.
Cuba, quarantine service in, 19; saving of life in, 30.
Cumston, Charles Greene, posterior colpocœliotomy for lesions of the adnexa and uterus; its indication and technique, 247.
Curette, a new, 397.
Curry, James Hart, death of, 505.
Curtis, B. Farquhar, cancer of the stomach and intestines, 161.
Curtis, Romaine J., death of, 861.
Cutler, E. G., perforation of a typhoid ulcer without fæcal extravasation, operation four hours after the first symptom, recovery, 968.
Cutler, Joseph L., death of, 622.
Cycling, hygiene of, 985; Ruskin's dislike of, 398.
Cystitis, agglutination by the patient's serum of the bacteria found in, 784; etiology of, 792; malarial, 950; suppression of urine following, 347; treatment of, in women, 506, 551; typhoid, 743.
Cytolytic sera, 144.

D

Da Costa, J. M., medical bequests of, 539; obituary of, 423.
Dacrocystitis aggravans, 665.
Dana, Charles L., pernicious anæmia and its relation to inheritance, 841, 999; the non-suppurative inflammations of the brain, with report of a case of hemorrhagic (malarial?) encephalitis, 1.
Dannemora, prison hospital at, 737.
Davies, M. J., crying of a child in utero, 195.
Davis, Edward P., treatment of the patient during the weeks previous to expected confinement, 605.
Davis, George E., a clinical study of the liver as a factor in elimination, and in the production of nephritis, 415.
Dayton, Hughes, aneurism of the arch of the aorta, 196.
Deaf children, care of, 269.
Deane, Louis C., a method for the determination of eye defects in school-children, with a report of 1747 examinations, 815.
Death, apparent, after suffocation, chloroform poisoning, or electric shock, restoration of life in, 760; sudden, probably due to pulmonary embolism, 740; sudden, shortly after operation, 264.
Decinormal salt solution, 738.
Degenerates in the army, 577.
Degeneracy, 34.
Delirium in the course of infective diseases, 855.
Delirium tremens, 824.
Delusion, a peculiar, 154.
Delusions, 400.
Dementia, senile, 708.
DeMund, Frederick Cornell, death of, 861.
Dermatitis vesiculo-bullosa et gangrænosa mutilans manuum, 586; venenata, 424.
Dermatology, static electricity in, 609.
Dermographia and anidrosis, 197.
Development, symmetrical, 1019; the crises of, 576.
Diabetes, 93; abdominal colic, and œdema, interrelationship of, 106; a blood reaction in, 264; a cured case of, 305; cutaneous manifestations in, 466; discussion on, 110; in children, 466, 825; in relation to life insurance, 306; mortality from, in New York City, 766; pancreatic, due to calculi, 144; pathology of, 306; potatoes in, 975; prognosis of, 105, 299; quantitative proportions of the carbohydrates in the urine in, 305; relation of surgery to, 384; tabes dorsalis in relation to, 788; treatment of, 1000.
Diabetograph, 587.
Diaphragm, echinococcus cysts of the domed surface of the, 536.
Diarrhœa, hot-weather, in India, 358; in the tuberculous, abdominal faradization for, 175; summer, in infants, treatment of, 225, 256.
Dietetic problems, 1020.
Digestive disorders, rest in bed in the treatment of, 940; organs, practical physiology of the, 182.
Digitalis, fat-free tincture of, 506.
Diphtheria, antitoxic globulins instead of the entire serum in the treatment of, 535; bacilli of, in healthy throats, 862; effects of petroleum on the bacillus of, 667; epidemic of, traced to the milk supply, 670; in the horse, 385; local treatment of, 879; management of, in small cities, 670; paralysis following, 905; quantity of antitoxin required in treatment of, 829, 1019; relapse in, 55; relation of, to contagious catarrh in fowls, 104; saline infusions in severe cases of, 703; shortening of the period of infectiveness, 470.
Diploma, the saving of a, 542.
Diprosopus, 68.
Dirt eating, anæmia of dyspepsia consequent upon, 741.
Diseases transmissible from the lower animals to man, 626.
Disinfection, methods of, 756.
Dislocations, early excision for irreducible, 874.
Doty, Alvah H., modern quarantine in its relations to passengers, crew, and cargo, 681, 754.
Douche, prophylactic, 536.
Drainage, surgical, 916.
Dropsy, cupping-glasses in the treatment of, 607.
Drug-store physicians, 677.
Dulles, Charles W., mumps in pneumonia, 68.
Dumbness, hysterical, the result of intoxication, 184.
Dunning, L. H., amenorrhœa, 133.
Dupuytren's contraction, 347.
Dust, transport of disease by, 224.
Dysentery, African remedy for, 431; colostomy for the cure of, 947; etiology of tropical, 384, 583; in Brittany, 995; in Finland, 1021; methylene blue in the treatment of, 705; specific cause of, 667; treatment of, 797, 826.
Dysmenorrhœa, belladonna in, 156.
Dyspepsia, remedy for, 188.
Dyspnœa, gastrectatic, 372

E

Eagleton, S. Potts, death of, 543.
Earache, treatment of, 718.
Ears, acute catarrh of the middle, facial paralysis in the course of, 256; anæsthesia of the semicircular canals of the, 987; diseases of the, in infancy and childhood, 983; diseases of the, in pernicious anæmia, 707; foreign body for many years in the external auditory meatus, 785, 984; fungus disease of the, 948; injury to the membrana tympani, 544; pilocarpine in the treatment of catarrhal adhesive processes in the tympanum, 906; pneumatocele of the auditory canal, 656; sympathetic disease of the, 950; treatment of furunculosis of the, 718; tuberculosis of the, 672; ugly, operative treatment of, 862.
Earth, age of the, 638.
Eccles, Symons, death of, 830.
Eclampsia, treatment of puerperal, 740.
Eczema, hot-air treatment of, 345; parasitic origin of, 305, 426, 695, 862; seborrhœic, of Unna, 985; strong solution of tar in, 479; treatment of gouty, 665.
Edebohls, George M., migrated ovarian and parovarian tumor, 245.
Edelmann, George, death of, 181.
Education, effect of modern, upon children, 759; medical, need of uniformity in the standards of, 138.
Edwards, Thomas P., death of, 61.
Ehrenfest, Hugo, a few remarks on the use of medullary narcosis in obstetrical cases, 967.
Einhorn, Max, on apparent tumors of the abdomen, 801.
Eisen, Gustav, preliminary report on the presence of and nature of parasitic amœbæ (cancriamœba macroglossa) in the epithelial carcinomata, 6.
Electric currents, generating and transforming, for therapeutic uses, 597; light as a therapeutic agent, 594; storage in human system, 378.
Electricity, displacement or wave current, 596, 597; in gynæcology, 426, 589,

596; static, in dermatology, 609; therapeutic use of alternating currents of high frequency and tension, 426.
Electrization, combined, 595.
Electrodes, 593.
Electrolysis, treatment of tumors by, 884.
Electrotherapeutic sins, 593.
Elephantiasis, a case of enormous, 153; congenital, 175.
Elliot, John W., perforation of a typhoid ulcer without fecal extravasation, operation four hours after the first symptom, recovery, 968.
Elliott, George H., death of, 1018.
Elliott, H. A., universal ankylosis, 795.
Embolism of the pulmonary artery, 136.
Emergency ration, trial of a, 780.
Emotion, physiological theory of, 535
Emphysema, general subcutaneous, 469.
Empyema, diagnosis of, in children, 1018; surgical treatment of chronic, 55.
Encephalitis, hemorrhagic (malarial?), 1.
Endocarditis, gonorrhœal, with congenital malformation of the mitral valve, 1005; orrhotherapy of malignant, 354; recovery from ulcerated, under the use of antistreptococcus serum, 184.
Endometritis, acute senile, 556.
Endotheliomata, 118.
Enteritis, chronic and tuberculous, treated with arsenic, 263; muco-membranous, 231.
Enterocolitis, 426; muco-membranous, treatment of, 155.
Enteroptosis with factitious urticaria, 55.
Epidemic, definition of an, 756.
Epiglottis, cyst of the, 345.
Epilepsy cured by operation upon the nose, 68; disorders of memory associated with, 509; due to cerebral abscess following typhoid fever, 470; heart disease in relation to, 940; influence of measles and erysipelas upon, 90.; treatment of, by Fleisig's method, 418.
Epileptic colony in England, 463; colony in Illinois, 944; idiocy, cure of a case of, 742; insanity, 1015; seizures, relation of uric-acid excretion to, 227; status, 837.
Epileptics, salt in the alimentation of, 227.
Epistaxis, unusual case of, 974.
Epithelioma, 624.
Epityphlitis, sequelæ of, 143.
Equilibrium, disturbance of, 864.
Erdmann, John F., report of three cases of intestinal obstruction due to Meckel's diverticula, 645.
Erythema circinatum, pemphigus with, 347; induratum scrofulosorum, 470; scarlatiniforme, 24.
Erythematous rash due to boric acid, 904.
Erythromelalgia following influenza, 976.
Ether anæsthesia in abdominal surgery, bronchial disease not always a contraindication to, 782; upright position for, in operations on the nose, throat, and ear, 622.
Eustachian tube, catheterization of the, 218.
Euthanasia, advocacy of, 471.
Evans, Edwin, death of, 302.
Eventration, case of, 703.
Everett, William, death of, 946.
Eyeball, massage of the, 825; spontaneous hemorrhage in the, followed by rupture, 305; treatment of infected perforating wounds of the, 304.
Eyeglasses, wearing of, 548.
Eyes, care of the, 639; cleansing of the nasal cavities before operation on the, 624; congenital defect of the, 782; disorders of the, due to auto-intoxication, 984; effect of electric light on the, 424; errors regarding the treatment of strain of the, from various causes, 581; etiology of phlyctenular affections of the, 625; lime or mortar injuries to the, 545; mental disturbances after operation on the, 466; method of determining defects in, in school children, 815; power of the, 280; relation of diseases of the, to those of the teeth, 576; tuberculosis of the, 672, 881.
Eyestrain as a cause of gastro-enteric neuroses, 739; common but unrecognized symptoms of, 62; headache from, 182.
Ewald, C. A., extrabuccal feeding, 241.
Exanthemata, shall children be kept from? 783.
Exophthalmic goitre, 425; fatal case of, 419; removal of the cervical sympathetic ganglia for the relief of, 574; treated by internal antiseptics, 473.
Experiments, inhuman, 279.
Exposition, International, awards of the, to American institutions, 381.

F

Facial neuritis associated with unilateral retro-orbital neuritis, 782.
Fæces, incineration in the disposal of, 684.
Fallopian tube, primary cancer of the, 102.
Famine in India, 159.
Fat embolism, 105.
Fatigue, effect of, in modifying the minute structure of the liver and kidneys, 298, 825.
Fear, morbid, 62.
Fecal intoxication, 268.
Fecundity, 69.
Feeble-minded, care of the, 559; physiological training of the, 384.
Feeding, extrabuccal, 241, 668; infant, see *Infant feeding*.
Feet, treatment of sweating of the, 719.
Fellows, Henry Barton, death of, 982.
Femur, delayed union of fracture of the, 456; intra-uterine fracture of the, 508; separation of the epiphyseal head of the, 740.
Fenger, Christian, testimonial banquet to, 822.
Fever, hysterical, 706; on the day of admission to hospital, 175.
Fibrolipoma, extirpation of, from the retroperitoneal and pelvic connective tissue, 185.
Field hospitals in war, 800.
Filaria sanguinis, photomicrographs of, 835; transmission of, by the mosquito, 17, 342, 357, 785.
Filter, a pocket and canteen, 156.
Filtration of the water supply, advantages of, 978.
Finlay, Charles, mosquitos and yellow fever, 867.
Finger, infection of, 623; plastic substitution for, of a toe, 1027.
Finney, Oswald B., death of, 141.
Fischer, Louis, infant feeding, 893.
Fisher, Charles S., observations on the gastric functions before and after gastroenterostomy, 366.
Fisher, W. C., a large ovarian cyst, 235.
Fistula in ano, 115; its relation to phthisis, 14.
Fitzpatrick, Thomas, death of, 27.
Flat-foot, pathogenesis of, in cases of varicose veins, 535.
Fleas as carriers of plague, 280.
Floersheim, Samuel, the use of the suprarenal capsule in diseases of the lower air passages, 774.
Flügge's theory and its application to surgery, 696.
Fœtus, perforation of the skull of a, intra partum, with favorable outcome, 575; prolapse of the intestines during labor, 584.
Food, adulteration of, 979; borax and formaldehyde as preservatives of, 143; refusal of, 827.
Foramen ovale, patent, in advanced life, 581.
Fordyce, J. A., some clinical observations on lupus erythematosus, 41.
Formacetone, disinfection by, 668.
Formalin, poisoning by, 706, 906.
Foster, Clarence E., death of, 901.
Foster, Frederick May, death of, 21.
Foster, Hal, the removal of thirty-five screw-worms from the nose, 975.
"Fourth disease," 345.
Fourth of July, accidents on the, 59.
Fractures, discussion on, 315; massage in the treatment of peri-articular, 469; modern treatment of, 499; subperiosteal, 903.
Fragilitas ossium in subjects with dark sclerotics, 226.
Freeman, Gerald, death of, 61.
Freudenthal, W., electric light—its physiological action and therapeutic value in tuberculosis of the throat and lungs, 647.
Früh, Carl D. S., faradic electricity in renal colic, 235.
Fruit, fatal bloom on the, 558.
Fruitnight, John Henry, death of, 1018.

G

Gall bladder and ducts, differential diagnosis in diseases of the, 761; spontaneous dilatations and ruptures of the, in adhesive supra-umbilical peritonitis, 428; surgery of the, 552, 799.
Gall-stones, etiology of, 583; medical treatment of 56; olive oil in the treatment of, 786; simulating cancer, 908; surgery of, 62; treatment of, 417, 585; treatment of the attack, 386.
Gall tracts, surgery of the, 610.
Gangrene, spontaneous, of the legs in childbed, 895.
Gant, Samuel G., fistula in ano, its relation to phthisis, 14.
Gaseous emphysema, 784.
Gasoline as a surgical detergent, 517.
Gasserian ganglion, excision of the, for epileptiform neuralgia, 904.
Gastrectomy, total, 507.
Gastric secretion, artificial modification of, 106; therapeutic application of, 146.
Gastritis, chronic, 880.
Gastro-enteric infections in infancy, 232, 206; neuroses, eye-strain as a cause of, 739.
Gastro-enterostomy, observations on the gastric functions before and after, 366; two cases of, 516.
Gastro-jejunostomy, unusual complications following, 104.
Gastroptosis, 843; treatment of, 989.
Gastrotomy, two cases of, 516.
Gauntt, Franklin, death of, 61.
Gauze carrier, 543.
Gelatin in the arrest of renal hemorrhage, 743.
Genius, Mr. Treves' definition of, 260.
Gestation, protracted, in an old primipara, 194.
Gilbert, Samuel F., death of, 423.
Gillespie, James S., death of, 141.
Gillette, William J., report of a case of Porro-Cæsarean operation, 96.
Gingivitis, chemical factor in, 345; from auto-intoxication, 303; treatment of, 345.
Gingivostomatitis with albuminuria, 798.
Girl, the American, 976.
Gish, Samuel H., death of, 260.
Glandular fever, cases simulating, 760; in an adult, 237; in epidemic form, 826.
Glaucoma, acute, with subhyaloid hemorrhage supervening upon unilocular retinitis albuminuria, 385; resection of the superior cervical sympathetic ganglia for, 665; secondary, 263.
Gloves, sterilization of rubber, 548.
Glycosuria in gastro-enteritis of the newborn, 705; in relation to life insurance, 306; metatraumatic alimentary, 305; prognosis of, 299; relation of kidney disease to, 789.
Goitre in France, 24; retrosternal, with grave dyspnœa, 510; treatment of simple, in young adults, 347.
Goldan, S. Ormond, description of new instruments: (1) lip retractor; (2) interdental mouth props, 438.
Goldspohn, A., two cases of intestinal obstruction following vaginal hysterectomy, and one after pelvic abscess, with a secondary operation in each case, 374.

Gold wire, use of, in operations for hernia, 574.
Gonococci, diplococci resembling, in the normal vagina of children, 175.
Gonorrhœa in relation to insurance, 97; treatment of, 99.
Gonorrhœal endocarditis, with congenital malformation of the mitral valve, 1005; joints secondary to ophthalmia neonatorum, 468.
Goorkhas, diseases of, 358.
Gout, 233; a function failure, 298; clinical study of, 427; diagnosis of, 585; pathogenesis of, 345, 351, 578, 584; some clinical aspects of, 721, 745.
Granville, Mortimer, death of, 989.
Gravel, prevention of, 666.
Graves, Schuyler Colfax, observations on subclavian deligation, 528.
Gray, Ethan E., a case of myxœdema, with treatment, 69.
Gray, Landon Carter, resolutions on the death of, 21.
Grier, Matthew J., death of, 739.
Growth, primary disorders of, 63.
Gunshot injuries, modern small-calibre, 739, 824.
Guam, sanitary condition of, 621.
Gymnastics, non-hygienic, 160.
Gynæcology, electricity in, 486, 589, 596; medical, 1023; resources of modern minor, 673; the value of thermal carbonated saline baths in, 811.

H

Habitations, essential conditions of healthy, 384; sanitation of, 34.
Hæmatemesis, gastrotomy for, 743; in the course of intestinal occlusion, 742; post-operative, 544.
Hæmatomyelia, 252.
Hæmaturia, treatment of malarial, 175.
Hæmoglobin, determination of, 632.
Hæmoglobinuria, 24, 358, 667; in Trinidad, 865; malarial, 696; peculiarly altered blood pigment in the urine in, 296; quinine, 1021.
Hæmophilia, gelatin in, 743; in the negro, 149.
Haffkine's plague serum, method of using, 741.
Hammond, Græme M., two unusual cases of aphasia, with special reference to the so-called naming centre, 1010.
Hands, disinfection of the, 226, 265, 304, 398, 733, 949; value of pedicled flaps in injuries of the, 707.
Hands, W. C., a case of sudden and unexpected delivery of twins, 69.
Hanford, Maria Upton, death of, 580.
Hanks, Horace Tracy, obituary of, 823.
Hanot's cirrhosis, 788.
Hanson, J. G., malaria coexisting with typhoid fever, 434.
Harris, Elias B., death of, 260.
Harvard Medical School, new site for, 699; Veterinary School, 860.
Havana, sanitation in, 981.
Hawaii Medical Association, 503.
Hayden, James K., extravasation of urine, 150.
Hay fever, preventive treatment of, 55, 62; treatment of, 104, 418, 467, 666, 947.
Haynes, Irving S., a consideration of the anatomical construction predisposing to inguinal and femoral hernia, and the measures to be taken in securing their radical cure, 566.
Haynes, S., position in labor, 511.
Hays, Benjamin K., an epidemic of typhoid fever, 974.
Headache from eye-strain, 182, 418.
Health reports of the Marine-Hospital service, 80, 120, 160, 200, 240, 280, 320, 400, 440, 480, 520, 560, 621, 680, 719, 760, 800, 840, 880, 920, 960, 1000.
Health resorts, necessary and reliable data upon, 292.
Hearing, cortical localization of, 987.
Heart, a case of pulmonary stenosis, 668; accentuation of the second sound in the pulmonary area, 616; action of the, in mitral stenosis, 347; acute dilatation of the, in influenza in children, 263; antecedents of disease of the, in children, 1019; beginning of idiopathic enlargement of the, 743; cancers of the, 741; clinical study of disease of the, 704; complications on the part of the, in rheumatism, 629; connective-tissue induration of the, 950; diagnostic difficulties associated with dilatation of the right ventricle, 53; diastolic expansion movement of the ventricles as a factor in compensation for disease of the mitral valve, 353; disease of the, bearing of, upon life insurance, 655; double beat of the, 418; endocardial murmurs of organic origin localized in the pulmonary area, 48, 72; functional diseases of the, 828; inhibition of the, as an aid in diagnosis, 543; lesions of the, following the acute specific fevers, 733; metastatic epithelioma of the, 834; minor forms of dilatation of the, 227; new physical sign in dislocation of the, 372; non-traumatic rupture of the, 116; physiological dilatation and the mitral sphincter as factors in functional and organic disturbances of the, 702; prevention of valvular disease of the, in cases of acute rheumatism, 704; pulmonary stenosis due to ulcerative endocarditis of the aortic valve, 834; relation of influenza to chronic disease of the, 137; suprarenal capsule in diseases of the, 582; treatment of disease of the, 467, 986; treatment of failure of the, in the aged, 665; tumors of the, 976; use and abuse of stimulants of the, 976; venous obstruction complicating disease of the, 72; wounds of the, 921.
Heat-stroke as a post-operative complication, 832; in India, 507; venesection in, 144.
Hemianopsia from embolism, 395.
Hemiplegia, uræmic, 951.
Hemorrhage, anæsthetic solution for, 199; concealed accidental, 143; in typhoid fever, decinormal salt solution in the treatment of, 426; post-operative, 711, 862; post-partum, 313; treatment of cholæmic, 199.
Hemorrhoids, new operation for, 901; simple operation for, 713; submucous ligature for, 113.
Hepatitis, acute dysenteric, 348.
Heredity and imitation, 519; in disease, 975.
Hernia, anatomical construction predisposing to, 566; gold wire in the radical operation for, 574; hypodermic cure of, 199; indications for operation in, 796; local anæsthesia in the radical operation for, 972; obscure abdominal pains in, 832; of the ovary and tube and the vermiform appendix, 192; radical cure of, 465; radical cure of inguinal, in women, 986; radical cure of inguinal, relative bearing of the conjoined tendon and the internal oblique muscle upon, 321; radical operation for oblique inguinal, 264; repairing the abdominal wall in ventral, 702; surgical management of umbilical, 670; the Phelps operation for, 441; treatment of, 515; treatment of strangulated, 115, 895; ventral, following laparotomy, 711.
Herold, Henry T., death of, 181.
Hervey, Edward Addison, death of, 701.
Hiccough, treatment of, 797.
High altitudes, alleged increase of blood cells in, 145; hygiene of, 640; practice of medicine and surgery in, 97.
Highmore's antrum, empyema of, of fifteen years' duration, 902; primary epithelioma of, 987.
Hill heart, 467.
Hill, L. L., wounds of the heart, with a report of seventeen cases of heart suture, 921.
Hip-joint, amputation at the, 674; congenital dislocation of the, 702; etiology of congenital dislocation of the, 256; instrument for operating on congenital dislocation of the, 956; treatment of tuberculous and purulent disease of the, 714.
Hoag, Clitus S., death of, 141.
Hobby, Harold E., death of, 662.
Hodgkin's disease, 192.
Holder, O. H., the pathology of lupus erythematosus, 43
Hoornbeck, Stephen E. D., death of, 580.
Horse sickness, 200, 948.
Horsley, J. Shelton, the treatment of necrosis of the entire shaft of a long bone, with report of a case, 604.
Hospital, a race-track, 867; abuse, 380; discrimination in the reception of patients by a, 558; economics, course of, at the Teachers' College, 540; suit for injuries received in, 259.
Hospital ship, a French, in China, 383; Japanese, 429; the *Maine*, 79, 477.
Hospitals, expenses of the London, 919; New York City public, proposed change in the management of, 896; private, and their management, 554; private, for transmissible disease, 258, 430.
Hot air in affections of the upper air passages, 305; in the treatment of eczema, 345.
Huber, John B., summer vacations for the poor, 628.
Hughes, A. W., death of, 867.
Hühner, Max, a simple method for writing prescriptions for children, 814.
Hulseberg, Frederick W., death of, 223.
Humerus, fracture of the greater tuberosity of the, 829; treatment of supracondyloid fracture of the, 1018.
Hussey, M. F., a case of placenta prævia with twins, 238.
Hygiene, domestic, 36; in New York City, 758; teaching of, 756
Hydrocephalus, acute internal, 784; congenital, of non-inflammatory type, 474; internal, following cerebrospinal meningitis, 706.
Hydrogen gas, weight of, 520; peroxide, therapeutic value of, 864.
Hydrotherapy in gynæcology and obstetrics, 427; in some common dispensary diseases, 788.
Hyoid bone, median osteotomy of the, 16.
Hyperacidity, fat diet in, 106.
Hyperchlorhydria, simple primary, 667.
Hypertrichosis universalis, 788
Hypnotism, use of, in general practice, 170.
Hypospadias, operation for, 124, 635.
Hysterectomy, abdominal, 428; abdominal *vs.* vaginal, 710, 915; for myoma, 344; vaginal, 313.
Hysteria, 224; etiology and cure of, 142; in the child, 50; in the male, 226; nature of, 709; painful anæsthesia in, 378; treatment of, 696.

I

Ichthyosis hystrix, electric-light treatment of, 673.
Idiocy, epileptic, cure of a case of, 742; infantile amaurotic family, 56.
Immigrants, ages of, 200.
Immunity, 468; study of, 427.
Incineration *vs.* earth sinks and chemical disinfection, 684.
Inebriety, curability of, by medical treatment, 715, 1013.
Infant feeding, 104, 182, 183, 232, 234, 591, 893; relation of scurvy to, 675.
Infant mortality in New York, reduction of, 541.
Infants, fever as a sign of unsuccessful nursing, 1006; weight curve in, 136.
Infection, theory of, 584.
Infections, local, boiling water in, 705.
Inflammation, nomenclature of, 537.
Influenza, 913; acute nephritis following, 668; cough in, simulating whooping-cough, 829; effect of, on the nervous system, 983; epidemic, 983; erythromelalgia following, 976; fibrinous bronchitis due to, 855; hydrotherapy

in, 983; in children, sodium benzoate for, 22; of the nervous system, 276; pathology of, 185; potassium bicarbonate in, 784; relation of chronic heart disease to, 137.
Ingals, Ephraim, death of, 1018.
Ingrowing toe-nail, treatment of, 796.
Inheritance, physiology and pathology of, 826; relation of pernicious anæmia to, 841, 909.
Insane, hospital for the, in Palestine, 858; isolation of the tuberculous, 578; surgery among the, 97.
Insanity, alleged increase of, 184; among lead workers, 544; contagious, 855; crime, and sexual function, correlation between, 698, 925; electro-therapy of, 599; epileptic, 1015; in Great Britain, 398; in the United States army, 701; in Virginia, 58; incipient, 377; legal and medical, 534; post-febrile, 182; prevention of, 818; traumatic, 425.
Insomnia, causes and cure of, 948, 984; treatment of, when due to arteriosclerosis, 940.
Insufflation of the œsophagus, stomach, and colon, diagnostic and therapeutic value of, 262.
International Congress of Deontology and Professional Medicine, 222.
International Congress of Gynecology and Obstetrics, the place of meeting of the, 619.
International Congess of the Medical Press, 258, 420.
International Medical Congress, 221, 229, 428.
Intestine, anastomosis of the, 345, 717, 739; atropine for obstruction of the, 144, 985; cancer of the, 161; obstruction of the, complicating appendicitis, 653; obstruction of the, due to Meckel's diverticula, 645; obstruction of the, following vaginal hysterectomy and pelvic abscess, 574; occlusion of the, by cancer of the colon, 985; perforation of a typhoid ulcer of the, without fecal extravasation, 968; traumatic rupture of the small, 787; treatment of obstruction of the, 786; syphilis of the, 145.
Intubation, case of prolonged, 298; effects of repeated, 835.
Intussusception, 839; in an infant, 306.
Iodide of potassium in ophthalmic practice, 825.
Iodism, antidotes for, 1013.
Iodo-parotiditis, 306.
Ipecacuanha, production of, 480.
Iritis 581.
Irwin, Crawford, death of, 622.
Isaacs, A. E., alveolar sarcoma of the uterus, 152.
Isaacson, Charles B., after-pains from extraction of teeth, 216.
Italy, students of medicine in, 699.

J

Jacobi, A., American medicine, 201, 710; on medical journalism, 300; presentation of a loving-cup to, 31.
Japan, letter from, 429.
Japanese navy, report of the surgeon-general of the, 430.
Jaundice due to gummatous infiltration, 625; pathogenesis of, 574; simple acholuric, 949; surgical importance of, 824.
Jaw, dislocation of the, in epilepsy, 104; jerk and jaw clonus, 627.
Jenkins, Norburne B., dislocation of the crystalline lens in immature cataract, 974; the spectacle and eye-glass habit, 431.
Johimbin, effect of, 787.
Johnson, Alexander B., some cases of acute appendicitis, 688, 716.
Johnson, Alexander H., death of, 702.
Joint, affections of the, the rheumatic and gouty diathesis in relation to, 443; gonorrhœal inflammation of, 585; neuropathic, 664; restoration of function to ankylosed, 695; septic and gonorrhœal, 664; treatment of tuberculous and purulent, 465; traumatic, 544; tuberculosis of, 673.
Jones, Hugh E., a new nasal-duct irrigator, 397.
Jones, Mary Dixon, insanity, its causes; is there in woman a correlation of the sexual function with insanity and crime? 925.
Jones, Noble W., the presence of virulent tubercle bacilli in the healthy nasal cavities of healthy persons, 285.
Jones, William, observations on the surgery of the gall tracts, 610.
Jones, William K., death of, 982.
Judkins, Charles P., death of, 61.

K

Kales, J. W., chylous ascites, 795.
Kashmir, letter from, 389.
Keays, Frederick L., the treatment of typhoid fever at the New York Hospital, 851.
Kebler, Frederick, death of, 945.
Keefe, D. E., notes on typhoid fever, with a report of fifteen cases, 808.
Kelley, Carl M., death of, 260.
Kelliher, Michael, death of, 739.
Kellogg, Edward L., hospital for scarlet fever and diphtheria patients, 430; sterilization of rubber gloves, 548.
Kemp, Robert Coleman, a glass hydrostatic-pressure irrigator for the urethra or bladder, 157.
Kendall, H. E., a case of carbolic-acid poisoning, with a question concerning asphyxia, 794.
Keratitis bullosa, 344; interstitial, 799; scrofulous, 263.
Kernig's sign in meningitis, 853.
Keyes, Edward L., Jr., the evidences of prostatic atrophy after castration, 81.
Kidneys, calculi of the, 908, 976; cystic degeneration of both, 54; determination of the functional integrity of the, by means of the freezing-points of the blood and urine, 828; diagnosis of tuberculosis of the, 679; eye affections associated with lesions of the, 256; functional diagnosis of diseases of the, 226; lipoma of the, 584; lymphosarcoma of the, 833; movable, reefing operation for, 582; movable, treatment of, 298, 996; surgical treatment of tuberculosis of the, 54, 943; treatment of primary tuberculosis of the, 586.
Kime, J. W., light as a remedial agent, 572.
King, Clarence, convulsions, 50.
King, George W., foreign bodies in the œsophagus, 643.
Kirkbridge, Thomas Story, death of, 141.
Knapp, Mark L., an improved stethoscope, 119.
Knee joint, amputation at the, 658; amputation at the, when the arterial circulation of the region is impaired, 961; intermittent hydrops of the, 711; suppurative inflammation of the, following a penetrating wound, 509; surgery of non-tuberculous affections of the, 506; tuberculosis of the, 294.
Knock-out drops, 999.
Knopf, S. A., neglected clinical opportunities in American medical centres, 36, 86; prize of the Berlin Tuberculosis Congress awarded to, 221.
Koplik's spots in measles, 54, 344, 840, 986.
Kurth, Henry A., chronic copper poisoning among artisans, 731.

L

Labor, chorea and leukæmia as indications for the induction of, 616; difficult, interference in, 22; management of normal, 629; position in, 511.
Laboratory research, relation of, to practical medicine 902.
Labyrinth, physiology of the, 733.
Lacrymal ducts, chronic inflammation of the, 703; electrolysis in stricture of the, 663; punctum, dilatation of the, 118.
Ladinski, Louis J., internal hemorrhage the result of traumatic rupture of adhesions due to acute appendicitis, with the report of a case, 924.
Lameness, intermittent, 782.
Lange, Karl, death of, 60.
Langmann, Gustav, poisonous snakes and snake poison, 401.
Language, international, 341.
Laparotomy, see *Celiotomy*.
Larimore, F. C., hernia of the ovary and tube and the vermiform appendix, 190.
Larkin, William R., death of, 662.
Larson, C. Frithiof, women medical graduates in Sweden, 67.
Laryngeal hypokinesis, hysterical, 268; nerve, recurrent, paralysis of the, 740.
Larynx, atresia of the, due to faulty intubation, 668; naked-eye diagnosis of cancer of the, 707; neuralgia of the, 906; papilloma of the, in children, 703, 799; pathology and treatment of toxic paralyses of the, 707; perichondritis of the, in typhoid fever, 348; polyp of the, with signs of pulmonary phthisis, 54; salicylic acid for pachydermia of the, 386; stenosis of the, due to injury of the thyroid cartilages, 703; tuberculosis of the, 671, 970, 988.
Lavage, indications for the use of, 797.
Lazear, Jesse W., death of, 543.
Lead poisoning among stonecutters, 940; encephalopathy in, 63; through the use of lead ointment, 220, 228; two cases of fatal, 469.
Leech, D. J., death of, 149.
Leg, technique of amputation of the, 743.
Leontiasis ossea, 696.
Leper colony at Robben Island, 696; in the Philippines, 222.
Lepers, disinfection of the mail of, 778.
Lépine, R., nature of hysteria, 709.
Leprosy in China, 677; in France, 239; in Germany, 878; in the Philippines, 341; in the United States, 756; treatment of, 545.
Letters from Beyrout, 28, 349; from Brazil, 29, 108; from Constantinople, 708; from Japan, 429; from Kashmir, 389; from London, 26, 65, 106, 148, 187, 228, 268, 306, 348, 388, 470, 510, 547, 588, 627, 668, 708, 743, 789, 829, 866, 906, 951, 988, 1022; from New Zealand, 269, 907; from Paris, 27, 107, 428, 589; from Peru, 590.
Leukæmia, 633; acute, 584; a disease resembling acute, 378; as an indication for the induction of labor, 616.
Leukocytosis, differential, 715.
Leukoderma in India, 266.
Leukoplakia buccalis, relation of, to syphilis and cancer, 985.
Levin, Isaac, pathological physiology or experimental pathology, its scope and significance in medicine, 327.
Leviseur, Fred. J., a new urethroscope, 38.
Ligamentopaxis, 590.
Light as a remedial agent, 572.
Lightning stroke, recovery from, 393.
Lincoln, Rufus P., death of, 861; obituary of, 901.
Linea alba, hernia of the, 1021.
Lingual tonsil, scissors for the, 118.
Linsley, J. H., the significance of the bacillus coli communis in drinking-water, 324.
Lip retractor, 438.
Lipoma of the plantar arch, familial, 428.
Lipomatous abdominal wall, retrenchment of the, 787.
Lippitt, T. M., wounded in Peking, 302.
Lister in Paris, 309.
Little, Seelye W., report of a case of fractured liver, 973.
Liver, accessory lobe of the, 834; clinical study of, as a factor of elimination, 415; contusions of the, 305; cure of a case of hypertrophic alcoholic cir-

rhosis of the, 488; fracture of the, 973; hepatic odor in abscess of the, 827; pathology of acute yellow atrophy of the, 177; rupture of the, 98; sarcoma and cirrhosis of the, 707; sequel of hydatids of the, 906; surgical treatment of hydatid cysts of the, 600; tropical abscess of the, 359.
Lloyd, Frederick Osborne, death of, 1018.
Lockwood, George Roe, gastroptosis, 843.
Locomotor ataxia, see *Tabes dorsalis*.
London, letters from, 26, 65, 106, 148, 187, 228, 268, 306, 348, 388, 470, 510, 547, 588, 627, 668, 708, 743, 789, 829, 866, 906, 951, 988, 1022.
Loomis, Henry P., some personal observations on the effects of intrapleural injections of nitrogen gas in tuberculosis, 481.
Los Angeles, consumptives in, 225.
Losdorfer's bodies in syphilitic blood, 176.
Losee, John E., death of, 1018.
Louisiana, care of lepers in, 140; local health boards in, 738.
Luckett, W. H., a new needle-holder that will not break needles, 177.
Lumbricoids, pseudo-meningitis due to, 176.
Lungs, abscess of the, 106; and spleen, percussion of the boundary between, 106; œdema of the, 231; suprarenal capsule in diseases of the, 774.
Lupus erythematous, 41; vulgaris, incision of, 534; vulgaris, *x*-rays in the treatment of, 783, 947.
Luxations, voluntary, 16.
Luzzatto, M., a cure of a case of hypertrophic alcoholic cirrhosis of the liver, 488.
Lymph node as a factor in diagnosis, 574.

M

Macalester, Richard K., balneotherapy as practised by the Indians, 79.
McCartee, Divie Bethune, death of, 141.

Miller, George L., a case of tuberculous intra-peritoneal effusion cured by incision and permanent drainage, 70.
Miller, H. T., fracture of the clavicle, resulting in rupture of the suprascapular artery (?), 973.
Minnesota, medical defence association for, 736.
Mississippi Valley Medical Association, 710.
Mock, E. V., dermographia and anidrosis, 197.
Mole, vesicular, malignancy of, 895.
Moor, William Ovid, the discovery of "ureine," the principal organic constituent of urine and the true cause of uræmia, 336, 471.
Morbific agent and reparative effort, 145.
Moreton, Henry, death of, 662.
Morphine, use of, in surgical practice, 575.
Morphinism among physicians, 919; treatment of, 303, 304, 1021.
Morrison, J. H., lingual tonsil scissors, 118.
Mortality, summer, 60.
Morton wave current, 596, 597.
Moschcowitz, Alexis V., the radical treatment of tuberculosis of the testis, 412.
Moser, W., a peculiar delusion, 154; how is motility in the red blood cells effected? 989.
Mosquitos, 558; distinction between anopheles and culex, 780; transmission of filaria by, 17, 342, 357, 785; transmission of malaria by, 63, 538, 669, 703, 704, 865, 879, 946, 1023; transmission of yellow fever by, 697, 703, 754, 858, 863, 867.
Mould infection in man, 23, 439.
Mouth props, interdental, 438.
Mouth, septic condition in the, as a cause of disease, 225.
Muehleck, George A., death of, 702.
Mulcahey, Dennis Dowling, death of, 423.
Mules' operation, 582.
Mumps in pneumonia, 68; pancreatitis complicating, 23.
Mundé, Paul F., external abdominal examinations during pregnancy and labor, 390; why gynæcologists are reluctant to use electricity, 589.
Munn, William H., death of, 506.
Murder, attempt at, by a youth, 509.
Muscular atrophy following slight traumatism, 208; hereditary spinal, in childhood, 985.
Mushrooms, 557.
Mutilations, inheritance of, 66.
Myasthenia, gastric, 1021; gravis, 806.
Myers, T. Halsted, sarcomatosis of the vertebræ simulating tuberculous osteitis in a case of pulmonary tuberculosis, 394.
Myokymia, 1021.
Myomectomy per vaginam, 224.
Myositis ossificans, 387.
Myotherapy, 348.
Myxœdema, a case of, 69; in childhood, 510.

N

Nævus, varicose osteo-hypertrophic, 218.
Nammack, Charles E., a case of pernicious anæmia, Hunter's treatment, autopsy, 493.

Naphthol, camphorated, poisoning by, 470.
Nasal cavities, empyema of the, 182; fossa, sarcoma of the right, with acute sinusitis and orbital cellulitis, 513; polypus, 733; sinuses, anatomy of the accessory, 742.
Nasal-duct irrigator, 397.
Naso-pharyngeal disease in children, 305.
Naso-pharynx, sarcoma of the, cured by injections of formalin, 655.
Navy, comparative physique of recruits for the, 999.
Neale, Richard, death of, 988.
Necrosis of the entire shaft of a long bone, treatment of, 604.
Nectrianine, 227.
Needle holder, a new, 157.
Neftel, William B., the treatment of tumors by electrolysis, 884.
Negroes in Mexico, 66.
Nelson, William J., death of, 701.
Nephrectomy, 76.
Nephritis, acute, following influenza, 668; interstitial, prophylaxis and management of, 182; rôle of the alloxuric bases in, 865; the liver as a factor in the production of, 415.
Nephrorrhaphy, 76.
Nervous conductibility and electric conductibility, analogy between, 628, 849.
Nervous diseases, gonorrhœal, 828; traumatic, 506; traumatic, diagnosis of, 499.
Neuralgia, epileptiform, excision of the Gasserian ganglion for, 904; surgical treatment of trigeminal, 509; trigeminal, cure of inveterate cases of, 975; typical form of laryngeal, 906.
Neurasthenia, 949; causes and treatment of some cases, 598; diagnosis of, 535; subjective symptoms of, 906; the blood in, 865; treatment of, 346, 696; uric acid in, 534.
Neuritis, alcoholic face and pupil in, 948; arsenical, 984; facial, associated with unilateral retro-orbital neuritis, 782; motor ganglion cells in peripheral, 385; multiple, 104; multiple, following pneumonia, 474; puerperal multiple, 346.
Neuron, doctrine of the, 964.
Neuroserum, 998.
Neuroses, gastro-enteric affections due to, 428; intoxications and infections in, 905; traumatic, 506.
Newark, diphtheria antitoxin plant in, 755.
Newborn, apparent death in the, 575; prevention of colds in the, 142.
New Brunswick Medical Society, 422.
Newman, Robert, electricity in gynæcology and the present reluctance of gynæcologists to use electricity, 486, 596; modifications of Bottini's instrument for the treatment of hypertrophy of the prostate by galvano-cautery, 77.
Newspapers, medical editor on the staffs of, 36.
New York Academy of Medicine, 591, 675, 792, 831, 955; section on medicine, 746, 916, 1024; section on obstetrics and gynæcology, 76, 750, 915; section on surgery, 716, 831, 996; ventilation at the, 658.
New York County Medical Association, 74, 758, 953.
New York, the health of, 819.
New York Hospital, new buildings of the, 945.
New York Medical Journal, change of ownership of the, 138.
New York Neurological Society, 473, 836, 876.
New York Obstetrical Society, 661.
New York Pathological Society, 115, 833.
New York State Conference of Charities and Correction, 822.
New York State Hospital for the Care of Crippled and Deformed Children, 980.
New York State Medical Association, 628, 670; fifth district branch, 110.
New Zealand, letters from, 260, 907.
Nitrous oxide, alleged death from, really due to apoplexy, 490.
Nome, disease at, 140.
Nose, affections of the, in relation to general diseases, 467; carbonic acid gas in affections of the, 54; foreign body in the, 949; importance of preliminary treatment for operations on the, 650; screw-worms in the, 975; sudden blindness following cauterization of the, 975; synechia of the, 987; stenosis of the, from defective septum, operation for, 350; tuberculosis of the, 975.
Nosebleed, unusual case of, 974
Noyes, Henry Drury, obituary of, 781; resolutions on the death of, 899.
Nucleic acid extracted from the tubercle bacillus, 117.
Nutrition and stimulation, 712; in infants, physiology of, 265.

O

Obesity, hygiene of, 378; medical supervision of "cures" for, 667; treatment of, 879.
Obstetric conjugate, an instrument for determining the, 156.
Obstetric fraud, 343; practice, asepsis in, 417; work, some life-saving measures in, 875.
Obstipation, 713; symptomatic diagnosis of valvular, 56; valvular, 114.
Œdema, circumscribed cutaneous, 266, 865; malignant, 585; of the skin, chronic diffuse, 626.
Œsophageal growths, gastrotomy for, 546.
Œsophagus, atony of the, 386; diverticula and dilatations of the, 788; foreign bodies in the, 643; idiopathic dilatation of the, 387; rupture of the apparently healthy, 183; stenosis of the, 508.
Oettinger, Bernard, an early experience with the rain bath, 270.
O'Hogan, Charles James, death of, 1017.
Oliver's sign in aortic aneurism, 864.
Omental torsion, 787, 831.
Operation without digital contact with the wound, 575.
Ophthalmia neonatorum, 631.
Opium inebriety, medico-legal relations of, 303; new sources of danger in the use of, 263; poisoning, permanganate of potassium in, 616.
Optic chiasm, lesions of the, 623.
Orbit, foreign bodies in the, 985; three cases of vascular tumor of the, 11.
Organization in the profession, need of better, 758.
Organotherapy, discussion on, 74; significance of certain cell problems in, 787.
Orrhotherapy, discussion on, 666.
Osteitis, syphilitic fibro-spongioid, 63.
Osteomalacia, 742.
Osteomyelitis, acute, 56; chronic proliferating, 65.
Osteopaths, annual convention of, 59.
Osteopathy, regulation of, 500.
Osteopsathyrosis, idiopathic, 97.
Otalgia, treatment of, 155.
Otis, Edward O., what are necessary and reliable data upon health resorts? 292.
Otitis media, danger of purulent, in advanced life, 407; media in infants, 534; media in its relation to the cranial cavity, 712; media purulenta, bacteriology of, 902; media, treatment of fungoid, 338; septic pyohæmic, 297; suppurative, carbolic acid in, 297.
Otitic lateral sinus disease, two cases of, 707; treatment of, 707.
Ovarian cyst, a large, 235; dermoids, histogenesis of, 876; tumor, large multilocular, 143; tumor, solid, 875; tumors, migrated, 245.
Ovariotomy for ovarian pain, 77; in cancer of the breast, 704, 705.
Ovary, composite teratoma of the, 550; conservative surgery of the, 314; fibroma of the, 554; internal secretion of the, 581; papilloma of the, with secondary deposits in the peritoneum, 116; plea for avoidance of exsection of the, in connection with operations upon diseased tubes, 702.
Overcrowding in the etiology of tuberculosis, 664.
Oxaluria, 979; experimental study of, 585.
Oxygen, subcutaneous administration of, 666.
Oysters, disease spread by, 639; phosphorus in, 462; some of the properties of, 557.
Ozæna, probably of sphenoidal origin, 544; purulent frontal sinusitis in, 733.

P

Pachydermia laryngis, salicylic acid in the treatment of, 949.
Page, C. I., recurrent trance, 236.
Pain, surgical, 303.
Pains, labor, carbonic-acid gas for the relief of, 76.
Palate, myxomatous endothelioma of the soft, 468; tumor of the soft, 324.
Palatine muscles, clonic spasm of the, producing a sound heard at a distance, 176.
Pancreas, histology of the islands of Langerhans in, 469.
Pancreatitis, acute, complicating mumps, 23; hemorrhagic, 23, 826; symptomatology and treatment of, 776.
Panton, A. C., a case of perversion of sexual instinct, 436.
Paralysis, diphtheritic, 905; double facial, 237; Duchenne-Erb type of, 876; facial, 986, post-diphtheritic, 544.
Paris, letters from, 27, 107, 428, 589; typhoid fever in, 18.
Park, Herbert, death of, 302.
Parotid gland, abscess of the, 225; lipoma of the, 705; therapeutics of the, 75.
Parotitis, recurring, in a healthy child, 654.
Parovarium, primary carcinoma of the, 452.
Parturition complicated by suppurating fibroids, 142.
Pasteur hospital in Paris, the new, 107.
Patella, structure, fracture, and refracture of the, 986; treatment of fracture of the, 497.
Pathological problems of the present day, 230.
Pathological Society of Philadelphia, 620, 700, 780, 943.
Pathology, biological studies with reference to, 865; experimental, 327.
Paul, Thomas M., intestinal obstruction complicating appendicitis, with the report of a case, 653.
Payne, Albert S., an acranial monster, 198.
Peabody, Elias S., death of, 141.
Pearsall, Samuel J., death of, 860.
Peckham, Frank E., tumor albus, 294.
Peery, E. W., a new curette, 397.
Peking, climate of, 360.
Pellagra, pathogeny of, 426.
Pelvic disturbances in women an unnoticed factor in the production of, 516; massage, 1,000; organs malignant disease of the, 556; suppuration, posterior coloptomy in the treatment of, 142; surgery, difficult and obscure pus cases in, 557; surgery, evil results following, 536; surgery, simple methods in, 555.
Pelvis, glass drainage tube broken off in the, 716; removal of inflammatory masses from the, 869; thrombosis in the veins of the, after operation, 507.
Pemphigus with erythema circinatum, 347.
Penis, gangrene of the, 712, 793; webbed, 350.
Pericarditis of Bright's disease, 176; suppurative, surgical treatment of, 664.
Perineal tears, immediate repair of, 344.
Perineum, repair of old lacerations of the, 155.
Periostitis, multiple typhoid, 626.
Peristalsis, stomach pump as a stimulant to, 386.
Peritoneum, anatomy, physiology, and pathology of the, 126; sarcomatosis of the, 833; tuberculous effusion in

the, cured by incision and permanent drainage, 70.
Peritonitis, diagnosis of tuberculous, 626; diffuse, suppurative, from gangrene of the appendix, 467; from perforation of the stomach wall by a toothpick, 909; general septic, 953; in the fœtus, 143; the blood in, 633, tuberculous, 116.
Permanganate of potassium in opium poisoning, 616.
Peru, letter from, 599.
Pest house, right of a city to establish, 738.
Phagocytosis, 586.
Pharynx, subacute tuberculosis of the, in childhood, 378; the atrophic, 624; toxic paralysis of the, 418.
Phelps, A. M., a new instrument for operating on congenital dislocation of the hip and other diseases of bone, 956; the Phelps operation for hernia and method of closing abdominal wounds, 441; tuberculous hip disease, 714.
Phenacetin, physiological action of, 267.
Philadelphia County Medical Society, 660, 700, 821, 901, 981.
Philadelphia Hospital, association of ex-residents of the, 944.
Philadelphia Neurological Society, 736, 900, 1016.
Philadelphia Pediatric Society, 659, 980.
Philippines, diseases prevalent in the, 958; leprosy in the, 222, 341; quarantine in the, 341.
Phillips, James Willoughby, death of, 506.
Phillips, Wendell C., a further report upon the use of pure carbolic acid in the treatment of mastoid wounds and chronic suppuration of the middle ear, 296.
Phlegmasia alba dolens, treatment of, 902.
Phototherapy, 185, 572.
Phthisis (see also *Consumptives*, *Pulmonary tuberculosis*, and *Tuberculosis*), feeding of patients with, 347; influence of wind on, 830; marriage of patients with, 587; psychology of, 587; relation of fistula in ano to, 14; results of open-air treatment of, in the Berlin homes, 159; some causes of failure in the climatic treatment of, 739.
Physical training, 517; therapeutic uses of, 798.
Physician, definition of the word, 39; evolution of the modern, 272; in politics, 857.
Physiological research, experimental therapy as an aid to, 229
Physiology, pathological, 327.
Pierson, William, resolutions on the death of, 21.
Piffard, Henry J., some applications of static electricity in dermatology, 609.
Pillsbury, B., poisoning by oil of wintergreen, 150.
Pistol, a self-loading, 999.
Placenta, origin of cysts of the, 64; prævia, Cæsarean section in cases of, 740; prævia with twins, 235; transmission through the, 257.
Plague, bacillus of, action of soil on the, 80; bacteriology of, 478, 741; clinical aspects of, in Oporto, 304; diagnosis of, 905; diagnosis of, from typhoid fever, 741; endemic centres of, 39; in various places, 19, 29, 30, 101, 179, 223, 269, 278, 302, 341, 342, 349, 382, 422, 429, 464, 470, 510, 541, 547, 557, 588, 622, 627, 669, 708; inoculations against the, 959; introduction and spread of, 23; laboratory for the study of, in New York, 737; lectures on, 988; Lustig's serum for, 340; precautions against, in New Orleans, 858; preparation of antitoxin from the peritoneal exudate of infected animals, 226; resistance of the bacillus of, to cold, 296; symptoms of bubonic, pneumonic, and septicæmic, 741.
Pleibel, Frederick W., death of, 946.
Pleural exudate, with the physical signs of pneumonia, 543.
Pleurisy, leucocyte count in, 987.
Pneumonia, abortive, 53; bacteriological examination of the blood in, 960; diet in the acute stage of, 510; ending fatally with a convulsion of uræmic origin, 73; etiology of acute lobar, 656; following laparotomy in the neighborhood of the diaphragm, 425, hydrotherapy in, 165, 664; in the aged, 920; in the obese, 227; meningitis complicating, 798; meningococcus producing, 667; mumps in, 68; orrhotherapy of, 902; saline injections in, 351, 584; serum therapy of, 581; treatment of, 104, 189, 232; varieties of acute, 184; venesection and injection of a salt solution in, 984.
Pneumothorax with a valve due to pleural adhesions, 588.
Pneumotomy with resection of ribs, 428.
Poisoners in olden times, 438.
Poisoning, acute, 864.
Poisons, chemical resistance of the body to, 508.
Polyorrhomenitis, 1021.
Polypus, nasal, 733.
Porcelain ware, alleged danger in, 599.
Porcher, W. Peyre, an impersonator of, 823
Porro-Cæsarean operation, 96.
Porter, William Henry, to what extent does "rheumatic and gouty diathesis" enter into traumatic joints, etc.? 443.
Post-Graduate Medical School in London, 269.
Post-partum hemorrhage, prevention and treatment of, 707.
Post-rectal or pre-sacral growths, 555.
Potassium chlorate, poisoning by, 176; iodide, effects of, on the upper respiratory tract, 543.
Poultice, substitute for the, 392.
Power, abuse of professional, 941.
Pozzi-Devillers duel, 27.
Practitioners' Society of New York, 72, 745, 908.
Pregnancy, diagnosis of extra-uterine, 552; external abdominal examinations in, 390; extra-uterine, differential diagnosis of, 673; repeated ectopic, 344; simulation of, 77.
Premature burial, a society for the prevention of, 139.
Prepuce, operations on the, 346.
Prescriptions for children, simple method of writing, 814.
Preston, George J., a case of double facial paralysis, 237.
Prize, Alvarenga, of the College of Physicians of Philadelphia, 579; award of the Middlemore, 275; award of the Moscow, 230; Craig Colony, for original research in epilepsy, 859; of the College of Physicians and Surgeons, 20, Samuel D. Gross, 980
Proliferation and phagocytosis, 586.
Prostate, a cystoscopic incisor of the, 998; calculus of the, 424; castration for, hypertrophy of, 81, 469; hypertrophy of the, modifications of Bottini's instrument for the treatment of, 77; relief of enlargement of the, 725; vasectomy for enlarged, 796.
Prostatectomy, perineal, 832.
Prostatitis, traumatic, 61.
Prostitutes, medical inspection of, 737.
Protective coverings, organic, 185.
Proteids, immunity against, 144.
Pruritus, relief of, 189; ani, treatment of, 114, 350.
Pryor, William R., puerperal sepsis, its pathology and treatment, 641.
Psychic factor in disease, 303.
Psychology preliminary to medical education, 36.
Psychosis accompanying chorea, 417; operative, 545; periodical, 836; treatment of, by repose in bed, 706.
Ptomain poisoning, 559, 795.
Puberty, hygiene and therapeutics of, in women, 827
Public speaking in the medical profession, 734
Puerperal eclampsia, 263; hot baths in threatening, 1019; treatment of, 740.
Puerperal sepsis, 641; as a notifiable disease, 311; nature and treatment of, 143; prevention of, 546, treatment of, 1003, 1021.
Pulmonary artery, acquired stenosis of the, 56.
Pulmonary tuberculosis (see also *Consumption*, *Phthisis*, and *Tuberculosis*), diagnosis of, 663; early diagnosis of, 459; in infancy and childhood, 714, 986; iodine in, 824; new diagnostic sign of, 388; nitrogen gas by intrapleural injection in the treatment of, 271, operation in cases of, 23; organotoxin in, 587; pneumonic complications in, 64; sanatorium treatment of, in England, 354; Schoull's treatment of, 718; significance of heredity in, 587; sodium cinnamate in the treatment of, 179; subcutaneous injections of oil of camphor for, 78; the modern treatment of, 563, 790; treatment of, 24.
Pulse intermittent, 584.
Pupil, a little known reaction of the, 864.
Purgation with opium, 303.
Purple, Samuel Smith, obituary of, 542; resolutions on the death of, 738.
Purpura hæmorrhagica, 666; peculiar case of, 1020; rheumatica, 576; rheumatica and angina, 905.
Pyelitis, calculous, nephrectomy for, 905.
Pyloroplasty, 276.
Pylorus, congenital hypertrophic stenosis of the, 425.
Pyorrhœa alveolaris as a cause of disease, 225; cruel method in the treatment of, 175; syphilitic, 303.
Pyosalpinx, review of thirty cases of, 544.
Pyrexias of hot countries, 145.

Q

Quackery, unbridled, 1016.
Quarantine, modern, 681, 754.
Quinine, action and value of, in malaria, 356.
Quintard, Edward, a few cases of erosions of the stomach, 409.

R

Rabies, diagnosis of, 509; in man, curable forms of, 218; in New York, 779; statistics of preventive inoculations in Paris, 461; theory of the Pasteur inoculation for, 227.
Rachitis, color of living bone, 707.
Railway accidents, 439; sanitation, 158, 519, 753.
Rain bath, an early experience with the, 270.
Ranney, Ambrose L., does "cross-eye" affect the general health? 90.
Ration in the British army, 240; of the soldier in the tropics, 78, 612, 977.
Rats, method of extirpating, 108, 520.
Raw-food eaters, 503.
Raynaud's disease a gangrenous type, 476.
Read, Louis W., death of, 739.
Reciprocity in medical licensure, 493; action of the New Jersey board looking toward, 140.
Recto-vaginal opening, combined, in the human subject, 143.
Rectum, cancer of the, 825; causes and treatment of non-malignant stricture of the, 625; diarrhœa in disease of the, 103; fistula of the, 744; intermittent fibrous polyps of the, 64; operation for prolapse of the, in women, 824, 873; stricture of the, 276; surgery of the, 113; treatment of abscesses around the, 713; treatment of prolapse of the, 947.
Red Cross Society in China, 180; reorganization of the, 100, the; Russian, 778.
Red nose, treatment of, 348.
Reilly, William F., death of, 662.
Renal artery, aneurism of the, 624; insufficiency, auto-intoxication from, 875.
Rest in bed in the treatment of digestive disorders, 940.

Rheumatic fever, 424; etiology of, 583.
Rheumatic state, family predisposition to various manifestations of the, 704.
Rheumatism, chronic, assimilative processes in, 146; differential diagnosis of chronic, 384; etiology of acute articular, 856; heart complications of, 629; in children, danger of heart lesions in, 705; pathology and etiology of acute, 298; pyogenic origin of, 875; sore throat of, 905; treatment of, 1019.
Rhinitis, atrophic, 385; fibrinous, 940; in childhood, 22; purulent, 297.
Rhodan in the nasal and conjunctival secretion, 425.
Rice, Nathaniel P., death of, 782.
Richardson, Everard Hamilton, perfect recovery following gangrene of the scrotum and penis, 793.
Richardson, J. J., a case of epilepsy cured by operation on the nose, 68.
Ringworm of the scalp, treatment of, 234.

Robinson, Byron, the peritoneum in anatomy, physiology, and pathology, 126.
Robinson, William J., subarachnoid cocaine anæsthesia, 744.
Rockwell, A. D., on the analogy between the nervous conductibility and the electric conductibility, and their relation to the functional neuroses, 849.
Rocky Mountain Interstate Medical Association, 100, 381.
Rodman, H., report of a case of carbolic-acid poisoning successfully treated with alcohol, 70.
Roentgen rays, differentiation of aortic aneurism and intrathoracic tumor by the, 468; errors caused by false interpretation of, 281; experience essential to the satisfactory use of the, 266; in diseases of the nose, throat, and neighboring organs, 218; in lupus, 783; in skin diseases, 947; in the study of fractures and dislocations, 232; new appliances for work with, 595; photography, 598; practical hints for workers in, 37; rôle of the tube in the therapeutic application of, 426; use of, in surgery, 317.
Rogers, Philip F., a case of enormous elephantiasis, 153.
Rome, Robert S., an instrument for determining the obstetric conjugate, 156.
Rooms, air of, 440.
Rose, A., treatment of gastroptosis, 989.
Rosewater, Charles, some points bearing on the medicinal treatment of appendicitis, 173.
Roth, Philip, death of, 662.
Rötheln, differentiation of, from measles or scarlet fever, 783.
Roumania, hospitals in, 239.
Royal College of Surgeons of England, centenary of the, 268.
Rubella and scarlet fever, differentiation from, of a disease resembling both, 735; confusion of two diseases under one name, 144.
Russel, Jacob P., death of, 622.
Russian army, tuberculosis in the, 679.

S

Sacro coxalgia, 668.
St. John, David, report of a case of Cæsarean section, 235.
St. John's Guild, jubilee of, 139.
St. Louis Academy of Medical and Surgical Sciences, 858.
Samoa, diseases of, 1027.
Sanatoria, psychical influences acting on patients in, 817.
Sanatorium treatment of tuberculosis, 354, 387.
Santiago de Cuba, sanitary condition of 549.
Saratoga County Medical Association, 620.
Sarcomatosis of the peritoneum, 833.
Sargent, George W., alcohol as antidote to carbolic acid, 236.
Satterlee, G. Reese, complete recovery following a severe compound fracture of the skull, 154.
Sausage poisoning, 666.
Savage, Henry, death of, 669.
Savell, Richard, death of, 709.
Savidge, Eugene Coleman, some aspects of medical gynæcology from the standpoint of the general consultant, 1023.
Sayre, Louis Albert, obituary of, 505; resolutions on the death of, 661, 823.
Scabies, treatment of, 626.
Scandinavian physicians, biennial congress of, 580.
Scapula, total excision of the, 62.
Scar, contracting, of the palm replaced by a flap from the abdomen, 702.
Scarlatina, a constant bacteriological result in, 185; and rubella, differentiation from, of a disease resembling both, 735; etiology of, 543; hospital treatment of, in New York City, 946; rash of, 783; unusual case of, 345.
Schlapp, M. G., the non-suppurative inflammations of the brain, with report of a case of hemorrhagic (malarial?) encephalitis, 1.
Schleich mixture, death from, 236.
Schmidt, Ernst, death of, 343.
School chairs, improperly constructed, 384.
School children, method of determining eye defects in, 815.
Schools, hygienic and medical inspection of, 34.
Schoull's treatment of pulmonary tuberculosis, 718.
Sciatica cured by snake-bite, 305; syphilitic, 817; treatment of, 575.
Sclerosis, multiple, etiology of, 136.
Sclerotics, dark, fragilitas ossium associated with, 226.
Scott, Preston B., death of, 506.
Scrotum, gangrene of the, 712, 793.
Scurvy, cause and prevention of infantile, 425; etiology of, 264; is it an infectious and contagious disease? 428; relation of, to artificial feeding, 675.
Seaman, Louis L., the soldiers' ration in the tropics, its use and its abuse, 612.
Secrecy, ethics of, in the learned professions, 184.
Semeleder, F., malaria and mosquitos, 1023; negroes in the Mexican Republic, 60; the poverty of tropical countries as a cause of the feebleness of the natives, 989; the soldier in the tropics, 389.
Seminal vesicles, thimbles for massage and stripping of the, 702; vesiculitis, relation of, to impotence, 262.
Senecio jacobæ, physiological action of, 576.
Senn, N., gift to Rush Medical College by, 737.
Septicæmia following angina follicularis, 426.
Sewage farm of Paris, 600.
Sexual development, abnormal, 424; function, insanity, and crime, correlation between, 698; perversion, a case of 436.
Shannon, J. R., dilatation of the lacrymal punctum, 118.
Sharp, C. Edwards, lightning stroke with recovery, 393.
Shiels, George Franklin, a race-track hospital, 867.
Shipps, William H., simple fracture of the shaft of the femur, with report on two cases of delayed union, 456.
Ships, infectious diseases in, 560.
Shock, prevention of, 207, 656.
Shoemaker, Joseph T., death of, 946.
Shoe-varnish, poisoning by, 574.
Shoulder, congenital dislocation of the, 303; prognosis of dislocation of the, 796.
Sight, cortical localization of, 987.
Sinus pyæmia, 665
Skene, Alexander J. C., obituary of, 61.
Skin, diseases of the, lantern-slide demonstrations of, 318; non-operative treatment of cancer of the, 983; sarcoma of the, 74; subtrochanteric amputation for diffuse carcinoma of the, 947; tuberculosis of the, 673.
Skoda's sign, 616.
Skull, arrested mental development following depressed fracture of the, 785; compound fracture of the, followed by recovery, 154; fracture of the, 786.
Sleep, physiology of, 424.
Smallpox and vaccination, 896; contagiousness of, 360; measles, and chickenpox, concomitant, 377.
Smith, Edward, death of, 946.
Smith, Franklin, death of, 622.
Smith, Stephen, on a case which illustrated conservatism in surgery; the liability of an ancient cicatrix to cancerous degeneration; a new method of amputation at the knee when the arterial circulation of that region is impaired, 961.
Smoke nuisance, 720.
Smollett on surgeons, 960.
Smyser, Henry L., death of, 506.
Snakes, poisonous, 401; treatment of the bites of, 615.
Society for the Study of Diseases of Children, 259.
Soldier in the tropics, 389.
South Africa, criticism of the British army medical service in, 19, 107, 148, 159, 223, 228, 240, 268, 278, 306, 343, 399, 463, 471, 510, 547, 627, 678, 829, 866, 942, 943, 951.
Southern and northern hemispheres, medical differences between the, 535.
Southern Surgical and Gynecological Association, 868.
Spanish-American War Nurses' Association, establishment of the, 421.
Sparks, George W., death of, 823.
Specialties, future of, 622.
Spectacle habit, 182, 262, 270, 431.
Spermin crystals, 386.
Sphenoidal sinusitis, endocranial complication of, 951.
Spina bifida, treatment of, 667.
Spinal cord, diseases of the, in syphilitic infants, 348; gumma of the, treated with enormous doses of potassium iodide, 515; non-tabetic lesions of the posterior columns of the, 298.
Spinal anæthesia, 344, 508, 521, 561, 577, 601, 615, 624, 674, 714, 740, 744, 750, 791, 799, 828, 862, 868, 937, 967, 992.
Spinal sclerosis, posterior, ocular symptoms in, 64.
Spine, caries of the, with abscess, 783; fracture of the, 263, 795, 987; rigidity of the, 775; sarcomatosis of the, simulating tuberculosis, 394; traumatic disease of the, 667; tuberculosis of the, 713.
Spirits, certain apparently injurious constituents of potable, 1020.
Spitting habit, municipal regulation of the, 664, 860.
Spleen and lung, percussion of the boundary between, 106; enlarged, with hepatic cirrhosis, 55; enlargement of, in children, 425, 535.
Splenectomy, a successful, 904; Splenomegaly, primary, 706.
Spoke-shave in the removal of septal spurs, 265.
Spondylosis, rhizomelic, 267.
Sponges, sterilization of, 997.
Sporothrix Schenckii, abscess due to, 586.
Sprains, treatment of, 863.
Sputum, examination of, for tubercle bacilli, 267; significance of tubercle bacilli and other bacteria in the, 57.
Squibb, Edward Robinson, death of, 701.
Squires, G. W., an unusual case of nosebleed, 974.
Stanton, Margaret, tuberculosis and its treatment, 529.
Starvation, death from, 346.
Stature and intelligence, 709.
Stebbins, Roswell O., a pocket and canteen filter, 156.
Stephen, Walker B., death of, 901.

Sterility in man, 136, 637.
Sterilization of sponges, 997
Stern, Heinrich, the mortality from diabetes mellitus in the City of New York, (Manhattan and the Bronx) in 1899, 766.
Stethoscope, an improved, 119.
Stewart, James Fleury, death of, 982.
Stillbirth, hydrostatic test of, 948.
Stillé, Alfred, medical bequests of the late, 659; obituary of, 542.
Stitch abscesses, 797.
Stokes, Sir William, death of, 388.
Stomach, cancer of the, 161, 267; connection between the disorders of the, and of the uterus, 534; diagnosis of cancer of the, 379; dilatation and prolapse of the, 517; disturbances of motility of the 703; disturbances of the, in relation to diseases of the chest, 690; effect of nutrient enemata on the secretion of the, 864; erosions of the, 409, 829; examination of the contents of the, 782; functions of the, before and after gastro-enterostomy, 366; hemorrhage from the, 516; influence of morphine on the secretions of the, 546; menstrual troubles in certain diseases of the, 706; moulds in the, 142; position of the, in chlorosis, 666; Queirolo's method of determining the boundaries of the, 467; receptive quiescence of the, during mastication, 739; treatment of cancer of the, 872; tuberculous ulcer of the, 587; ulcer of the, 231, 305, 351, 419, 467, 551, 627, 917.
Stone, B. H., the significance of the bacillus coli communis in drinking-water, 324.
Stone, R. M., a death from the Schleich mixture, 236.
Storer, F. B., universal ankylosis, 907.
Stoughton, James, death of, 383.
Strabismus, effect of, on the general health, 90; management of, 674; necessity of early treatment of, 350; time to begin treatment of, 399; transient spastic convergent, 347.
Stretcher for army use, 78.
Stricture, urethral, remote results of structural lesions in, 304.
Strychnine, neutralization of, by the animal tissues, 655, 740.
Study, J. N., a case of Hodgkin's disease, 192.
Stupor, a case of protracted, 904.
Sturgeon, William H., death of, 662.
Styloid process, dislocation of the, 984.
Subarachnoid space, 62.
Subclavian artery, deligation of the, 528.
Subphrenic abcess, 275; following appendicitis, 458; resulting from a traumatic suppuration of the pancreas, 145.
Sugar as an oxytocic, 425.
Suggestion as a therapeutic agent, 425.
Suicide, causes of, 777; increase in, 617; in the French army, 503; observations on, 985.
Sultan's fête, medical aspects of, 709.
Summer vacations for the poor, 628.
Sunstroke, deaths from, at Aldershot, 158.
Suprarenal bodies, hemorrhages of the, 268; in diseases of the lower air passages, 774; in hay fever, 947; sarcoma of the, in an infant, 509; therapeutics of the, 74, 715.
Surgeon in the 19th century, 308.
Surgery, limitations of operative, 874.
Surgical operations, care of patients during, 207.
Sutures, metallic, 1015.
Sweat-shops, spread of disease by, 560.
Sweden, women medical graduates in, 67.
Swindler, arrest of a, 900.
Symblepharon, treatment of, 675.
Symphyseotomy, 632; subcutaneous, 744.
Syncope, significance of, 940.
Syphilis, calomel ointment in, 106; cerebral, 142; intervention of the dentist in the treatment of, 786; intestinal, 145; Losdorfer's bodies in the blood in, 176; malignant precocious, 348; of the upper air tract, 861; of the uveal tract, 182; origin of, 719, pathology of the initial sclerosis in, 346, pseudo-keloid following, 16; relation of, to tuberculosis, 387; slow pulse in, 100, spinal, 668; the Justus test in, 951.
Syphiloma, treatment of initial, 377.

T

Tabes dorsalis, co-ordination exercises in the treatment of, 424; cutaneous hyperæsthesia in, 427; diabetes in relation to, 788; early diagnosis of, 226; etiology and therapy of, 264; nasal crisis in, 428; recognition and management of, 514.
Tachycardia following typhoid fever, 225, 304; paroxysmal, 62.
Tænia flavopunctata, 983.
Taft, Charles S., death of, 1017.
Tailless mice, alleged breeding of, 66.
Talipes calcaneus, treatment of, in young children, 465.
Talmey, B. S., chorio-epithelioma malignum, 121; primary carcinoma of the parovarium, 452.
Tea, adulteration of, in Europe, 479.
Tear passages, surgery of the, 142.
Teeth, after-pains from extraction of, 216.
Temperance Congress, International, 65.
Tendon suture, 405.
Test-meal, a new, 783.
Tetanus, 587; following poisoning, 906; orrhotherapy of, 194, 468, 904; peculiar form of, 265; recovery from, 663; traumatic, complicated by intestinal obstructions, 468; treatment of, 62.
Tetany due to auto-infection, 910; gastric, 509.
Therapeutics, a mistake in, 894; rational, 500.
Thienhaus, Otto, appendicitis larvata and inflammation of the right broad ligament, tube, and ovary, 531.
Thirst, control of, 638.
Thompson, Guion, practical hints for *x*-ray workers, 37.
Thrombosis in the veins of the pelvis and lower extremities after operation, 507.
Thymus gland, therapeutics of the, 75.
Thyroid gland, acute enlargement of the, 24; therapeutics of the, 54, 74.
Thyrotomy, indications of, 304.
Tissues, experimental repair of, 705
Tobacco, use of, by soldiers in active service, 958.
Toboldt, A. L. A., death of, 901.
Tongue, black, 646; furring of the, in health and disease, 385.
Tonsillar diseases, acute, and their sequelæ, 143.
Tonsillitis, glandular complications of acute, when accompanied by influenza, 224; septicæmia following, 426; treatment of, 717.
Tonsils, concealed tuberculosis of the, 55; effects of enlarged, 417; hypertrophy of the, 824; hypertrophy of the pharyngeal, 739; infection through the, 297, 670; lingual, 466; primary epithelioma of the, 55; ulcerations of the, 297.
Toxicity *vs.* septicity in the infectious pathogenic bacteria, 507.
Toxins, effect of repeated injections of, on metabolism, 427.
Trachea, multiple ossified enchondroses of, 865.
Tracheloplasty, 712.
Tracheotomy, rare complication in, 105.
Trance, recurrent, 236.
Transfusion, 470.
Traumatism and infection, 229; etiological significance of, 742; psychical, death following, 545.
Travel, therapeutics of, 303.
Tremor, forms and clinical character of, 895.
Trichinosis, blood examinations in the diagnosis of, 634.
Trigger finger, 826.
Trimble, William B., treatment of fractured patellæ, 497.
Triplets, two sets of, 698.
Tropical diseases, instruction in, 503.
Tropics, improvement of sanitary medical practice in the, 359, poverty of countries in the, causing enfeeblement of the natives, 989, some problems of medicine in the, 625; the soldier in the, 359; the soldier's ration in the, 612.
Tubal disease, massage in the treatment of, 64.
Tubercle bacilli, dissemination of, by cows coughing, 950; methods of identification of the, 226; virulent, in the healthy nasal cavities of healthy persons, 285.
Tubercle tax on alcohol, a proposed, 439.
Tuberculin, diagnostic value of, 587.
Tuberculosis, British Congress on, 301, buccopharyngeal, 786; cancer in relation to, 808; cerebral, in children, 16, climate for, 664; climatic treatment of, 729, congenital, 225; consanguinity as a factor in the etiology of, 354, Courmont's serum reaction in the early diagnosis of, 63; cured peritoneal, in children, 545; diagnosis of peritoneal, 626; earliest signs of, 477; early diagnosis of, 387; educational and legislative control of, 587, electricity in the treatment of, 594, epididymotesticular, treated by ligature of the spermatic cord, 585; erythemas of, 386; etiology of, 593; fight against in France, 393; infection of, through milk and dairy products, 105; infectiousness of, 539; in the Russian army, 679; intrapleural injections of nitrogen in, 451; latent, of a pharyngeal tonsil, 175; nasal, 975; nasal cough in, 828; nature treatment of, 862; occupation in relation to, 465; of bone, injection for, 796; of the ear, 297, of the eye, 881; of the knee, 294; of the testes, radical treatment of, 412; palladium chloride in the treatment of, 388; pharyngeal, in childhood, 378; precautions against in Germany, 944, prognostic value of the diazo reaction in, 468; prophylaxis of, 864; pulmonary see *Pulmonary tuberculosis*; raw-meat cure of, 699; renal, diagnosis of, 679, renal, surgical treatment of, 942; sanatorium treatment of, 746; serum reaction in the diagnosis of, 986, sodium cinnamate for, 903, spinal, 713, spread of, in milk, 757, symposium on, 671; therapeutic value of electric light in laryngeal and pulmonary, 647, treatment of, 529; treatment of articular, 465; treatment of laryngeal, 970, 988; treatment of primary renal, 586; trophic changes in, 424; vesical, 742; where the danger lies in, 903.
Tuberculous lesions from a clinical point of view, 508, 514.
Tubo-ovarian abscess, management of, 556; disease, how best to deal with it, 765.
Tumor albus, 294
Tumors, distribution of connective tissue in, 468; electrolysis in the treatment of, 854; post-rectal or pre-sacral, 555.
Turbinate, bullous enlargement of the middle, 663.
Turbinated bodies, hypertrophy of the, 544.
Turck, Fenton B., the care of patients during surgical operations; with some methods of preventing shock and infection, 207.
Turnbull, Lawrence, death of, 701.
Turpentine, action of the oil of, 184.
Tuttle, George H., a new vaginal douche, 838.
Twins, sudden and unexpected delivery of, 69.
Tympanum, fibroma involving the, 266.
Typhoid and colon bacilli, a pathogenic group intermediate between, 347.
Typhoid bacillus, detection of, in water, 78; differentiation of, from the colon bacillus, 104.
Typhoid fever, 916; agglutinating properties of the blood of a healthy infant born of a mother with the disease, 105; among soldiers, 158; among the Brit-

ish troops in South Africa, 98, 279; and appendicitis, diagnosis between, by means of iodine reaction, 861; antiseptic and eliminative treatment of, 142, 378, 575, 655; bowel lesions of, 1020; coexisting with malaria, 434; cystitis in, 743; development of, during the course of active syphilis, 588; diagnosis of, from plague, 741; eliminative and antiseptic treatment of, 513; epidemics of, 821, 974; feeding in, 824, 854; fœtal and infantile, 986; gangrene of the leg following, 518; hydrotherapy for, in private practice, 634; in children, 469; in New York, 900; in South Africa, 398; intestinal paralysis in, 396; laryngeal manifestations of, 22; mortality from, in South Africa, 438; notes on, 808; pathology and treatment of, 789; perichondritis of the larynx in, 348; periostitis complicating, 626; peritoneal infection in, 22; preventive inoculations, 144, 219, 228, 355, 385, 501, 620.; prognosis in, 818; psychosis of, 949; puttee (?) paralysis after; 785; several attacks of, 342; self-limitation of, 895; soup diet and rectal irrigations in, 775; sterilization of excreta in, 826; tachycardia following, 225; treatment of, 22, 664, 1020; treatment of, at the Johns Hopkins Hospital, 623; treatment of, at the New York Hospital, 851; Widal tests for, at the New York quarantine station, 898; with unusual features, 62.
Typhoid gangrene, bilateral, 387.
Typhoid-like disease, caused by a typhoid-like bacillus, 346.

U

Ulcer, rodent, resorcin in, 393.
Umbilicus, infection through the, 417.
University of Dallas, Texas, 661.
Uræmia, the cause of, 336, 471; venesection for, 144.
Ureine, the discovery of, 336, 471.
Ureters, anastomosis of, with the intestine, 262; catheterization of the, 107; pelvic pain from calculi in the, 54; total extirpation of the, 507, 996.
Urethra, forward dislocation of the, 634; hydrostatic-pressure irrigator for the, 157; rupture of the, 782; treatment of resilient stricture of the, 865.
Urethroscope, a new 38.
Urinary infection, ascending, due to the bacillus pyocyaneus and proteus vulgaris, 506; organs, systemic infection in diseases of the, 264.
Urine, bile pigment in the, in cardiac disease, 144; dextrose in, 110; excretion of, with diminished kidney weight, 62; extravasation of, 150; extravasation of, following stricture of large calibre, 149; floaters in the, 103; new disease with a specific action of the, 304; pigments of the, in their pathological aspects, 866.
Urogenital tuberculosis, surgical treatment of, 672.
Urticaria, factitious, with enteroptosis, 55.
Uterus, alveolar sarcoma of the, 152; cancer of the, 711; connection between the disorders of the, and of the stomach, 534; dilatation of the cervix by means of a modified Champetier de Ribes balloon, 361; electrical treatment of fibroids of the, 984; enormous fibroma of the, 642; fibroids of the, 224, 312; fibroids of the, complicating pregnancy, 385; fibroids of the, mortality of hysterectomy for, 344; hysterectomy for cancer of the, 22, 915; inversion of the, of three years' duration, 315, 863; myomata of the, 750, 953; operative treatment of prolapse of, in elderly women, 817; osteofibroma of the, 870; prolapse of the, hysterectomy for, 77; results of vaginal hysterectomy for cancer of the, 952; round ligament ventro-suspension of the, 549, 590; surgical treatment of displacements of the, 553; treatment of cancer of the, 799; treatment of complete prolapse of the, in elderly women, 798; treatment of fibroids in the non-pregnant, 555; treatment of inflammation of the adnexa by water at 60° C., 827; treatment of prolapse of the, 585; treatment of retroversion and prolapse of the, 517; treatment of rupture of the, 509; treatment of spasmodic contraction of the, 468.
Uvula, superimposed, 1018.

V

Vaccinal immunity, extreme brevity of, 742.
Vaccination, abnormalities of, 957; compulsory, 590; eruptions, 263; in Paris, 1026; utility of, 896.
Vaccinator charged with assault, 540.
Vaccine lymph as an alterative, 914; club-shaped bacterium in, 105; infection of the lips by, 880; influence of temperature on, 755; micro-organisms of, 863.
Vagina, hot-water injections in the, 954.
Vaginal douche, a new, 838.
Vaginitis, treatment of, 189.
Valentine, Ferd. C., hypospadias operated on by Beck's method, 124.
Varicose veins, operative treatment of, 1006; results of operation on, 1019.
Varix, 904.
Vas deferens, latero-lateral anastomosis of the, 298.
Veins, wounds of, 796.
Vena cava, compression of the superior, 588.
Venesection and saline infusion, 638.
Vertigo of doubtful origin, 745.
Vesiculitis, acute seminal, 507.
Veterinary surgeons in the U. S. army, 759.
Viscera, transposition of, 105.
Viscin, therapeutic application of, 742.
Vitiligo in Peru, 590.
Vitreous, implantation of an artificial, 582.
Voice, physiology of the production of the, 266, 574.
Voorhees, James D., dilatation of the cervix by means of a modified Champetier de Ribes balloon, 361.
Vulva, diffuse non-malignant papilloma of the, 554.

W

Walters, J. S., death of, 782.
War, mortality in, 479.
Ward, George S., death of, 21.
Ward, William Spencer, obituary of, 383.
Warts cured by vaccination, 544.
Water, extemporaneous purification of, 680; proper use of, 543; supply, filtration of the Albany, improved health conditions following, 978; supply in military camps, 719; supply of New York, filtration of the, 856, 897; supply, pollution of, 755.
Waterman, William B., death of, 343.
Weather, influence of, on infectious disease, 426.
Welch, George K., some remarks on medicine in 1800, 1001.
Welles, Samuel Russell, death of, 141.
Wens, interstitial injection of ether for, 105.
West, Benjamin Hussey, death of, 622.
Wheelock, George G., presentation to, 822.
White, Moses C., death of, 701.
White, Richard H., death of, 505.
Whooping-cough, bacteriology of, 346; treatment of, 976; treatment of the paroxysmal stage of, 785.
Wiggin, Frederick Holme, defense of suits for alleged malpractice, 511.
Williamson, George Edward, death of, 27.
Wind, influence of, on phthisis, 830.
Wintergreen, poisoning by oil of, 150,
Wise, Richard A., death of, 1017.
Woman medical graduate, the first, in Germany, 999.
Woman's Hospital, nurses' home for the, 859.
Women, medical graduation of, 759.
